Another factor in this difference in the incidence of bovine infection in urban and rural inhabitants which must be considered is an immunological one. Infection with the human type of bacillus must be less common in the country than in the towns, and the rural dweller therefore escapes this type of infection, he consequently develops no tuberculo-immunity, and thus is more liable than the town inhabitant to bovine infection. Indeed, it has been suggested that the presence of bovine bacilli in milk may serve as an immunizing agent in the human subject. This is, however, a dangerous doctrine, for neither the dose nor the virulence of the bacillus is under control, and tuberculous disease, often fatal, may result. For example, applying the bovine percentage—namely, 11.1—which we obtained in Scotland during 1943–4 for meningitis to the 1,033 meningeal deaths recorded for these years by the Registrar-General (Scotland), it can be computed that 115 of these were due to infection with the bovine bacillus. Similarly applying the bovine percentage of 33.8 for surgical tuberculosis obtained in the same investigation to the 1,043 cases of surgical tuberculosis notified in these years, it is estimated that 6,906 of the cases were caused by the bovine bacillus.

Reinfection tuberculosis due to the bovine bacillus is unusual, as it is not common to find post-mortem evidence of fresh infection in cases of tuberculosis of the abdominal or cervical glands when old lesions already exist. This is a marked contrast to the lung, where the finding of a small healed primary focus, usually without glandular involvement and more recent reinfection tuberculosis, is not uncommon. It is worthy of comment, however, that even in healed cervical and abdominal glands viable tubercle bacilli may still be present; indeed, we have been able to isolate bovine bacilli from calcified abdominal glands. From such an apparently healed focus tubercle bacilli may escape and cause secondary lesions in bones, joints, urogenital system, etc., years after the primary infection in the glands has taken place.

2 Respiratory Infections

Respiratory tuberculosis of bovine origin is rare, accounting for 3.6% in our necropsy series in children (Table I), and for 5.7% of cases in Scotland and 1.9% in England, Wales, and Eire in the collected figures for all ages reported by Griffith and Munro (1944). In our series bovine bacilli were isolated from the primary lung foci and related tracheo-bronchial glands, thus there is little doubt that the infection was of respiratory origin. Infection in these cases was probably derived from open cases of pulmonary tuberculosis due to the bovine bacillus.

Conclusion

The duty of every medical man is first to prevent disease, that is not possible, to cure, and if that is impossible, to alleviate. How is this dictum to be applied to tuberculosis? As regards prevention—human infection is the more difficult to control as there are so many known and unknown carriers of the disease in our midst. As Osler (1905) remarked "The germ of tuberculosis is ubiquitous; few reach maturity without infection, none reach old age without focus somewhere." It is obviously impossible to segre-

gate all those who may spread the disease, but in factory, in workshop, in school, and in college mass radiography together with adequate clinical examination can play an important part in excluding foci of infection, especially among the young susceptible 15-to-25-years age group, in which tuberculosis is the main cause of death. But mass radiography applied indiscriminately to the population at large will achieve little if we cannot admit to hospital all those who are liable to disseminate the disease, both the young incipient and the old chronic case. Little is eventually to be gained in the control of the disease by dismissing from hospital the old chronic to provide a bed for the young case that will only result in further spread of the disease. All this is a problem for preventive medicine. Higher standards of living, housing, nutrition, and recreation must also play their part; these are problems for social medicine. These measures may help to reduce the incidence of the disease but will not completely eradicate it.

Bovine infection is the easier to control, and in this agriculturists and veterinarians have already accomplished much. The ideal, of course, is that all milk for human consumption should come only from attested herds, but this is a long-term policy and in the meantime some universal form of adequate heat treatment seems to be the only solution, particularly in view of the bulking of our milk supplies. This is no counsel of despair, as it must be emphasized that in addition to tuberculosis there are many other equally important milk-borne diseases which are preventable by heat-treatment, even though all milk eventually comes from attested herds.

Prophylactic vaccination with BCG is still a controversial question, and over 20 years of trial has left the medical profession in a state of confusion as regards its efficacy. Many reports, chiefly from Scandinavia and more recently from America (Aronson and Palmer, 1946), and the recent Memorandum to the Minister of Health (Tyler, 1946) testify to the advisability and the adequacy of this measure. It is uncertain, however, that in a mixed population such as ours the same results would hold as elsewhere, particularly as tuberculosis is such a prevalent disease with us, and frequent infection must be the lot of us all. The discovery by Petroff *et al* (1927–8) that BCG could dissociate into avirulent R and virulent S forms raised doubts in the minds of many regarding the use of a living vaccine. No definite case of tuberculosis has, however, yet been proved as resulting from the use of properly prepared BCG vaccine. Vaccines of killed bacilli have been employed with apparent success by Goodwin and Schwentker (1934), Opic *et al* (1939) and Wells *et al* (1944). As in all tuberculosis research, it will be long before we can assess and pass a final judgment on the efficacy of BCG vaccination. This interval must be at least 15 to 25 years in order to allow us to judge its efficacy in the young adult age group, in which at present tuberculosis is such a serious problem. Meanwhile, BCG may serve a useful function until chemotherapeutic or immunological research provides us with something as reliable for the cure of tuberculosis as penicillin has been for pyogenic infections. In his Memorandum Tyler (1946) has given all the essentials for a scheme of prophylactic vaccination. It is hoped that those in authority will carefully consider his suggestions, as the disaster at Lilbeck is still fresh in our minds.

With regard to the cure of established tuberculous disease, nothing can be added to the valuable contribution which D'Arcy Hart (1946) has made to the chemotherapy of tuberculosis. Streptomycin is still under trial as a curative agent, and the results of these trials are awaited with interest.

The expenses of this research were paid by a grant from the Medical Research Council

OXYGEN POISONING IN MAN

BY

KENNETH W DONALD, D S C, M D, M R C I

Late Senior Medical Officer, Admiralty Experimental Division
Unit Chief Assistant Medical Professional Unit
St Bartholomew's Hospital

PART II

Signs and Symptoms of Oxygen Poisoning

The available knowledge of the signs and symptoms of oxygen poisoning in man at the beginning of these experiments was extremely scanty. Only about 12 cases of exposures where acute toxic symptoms had occurred had been described. It is not certain that Bornstein suffered from oxygen poisoning (see below). All these exposures were in compressed air, and with the exception of Bornstein all subjects were seated and at comparative rest. The British Naval instructions at this time (1905) read as follows: "Symptoms: Tingling of the fingers and toes and twitching of the muscles, especially round the mouth (warning symptoms). Convulsions followed unconsciousness and death if a remedy is not taken." The US Naval instructions stated: "The first signs of toxicity are the flushing of the face, nausea, dizziness, muscle-twitching. A feeling of being irritable and a loss of excitement may follow. As the pressure is increased, nausea, vertigo, and, finally, unconsciousness and convulsions ensue."

It was inevitable, with the limited data available, that these instructions were brief and not altogether accurate. Tingling of the fingers and toes had not been reported in any experiment, but was inferred from its occurrence in the aura of idiopathic epilepsy. In the first large series of human experiments, described in this article, a more complete picture of the syndrome of oxygen poisoning in man has resulted. Most of the signs and symptoms described in the pre-convulsive stage, in the auras, or the non convulsant equivalents of epilepsy have been encountered. As in that disease, the total of signs and symptoms is now known. Yet—again as in epilepsy—the individual pattern of signs and symptoms varies enormously within this framework. Signs and symptoms as experienced when the subjects were breathing pure oxygen in compressed air are first described, as the subjects' experience was more normal and careful direct observation possible.

Facial pallor usually occurs a few minutes after beginning of the exposure. It varies from person to person in degree and time of onset. The degree of facial pallor is in no way indicative of the subject's sensitivity or of the impending end-point. Fasciculation of the lips or face is often seen early in the experiment and continues throughout the exposure. This has been partially attributed to fatigue caused by the mouthpiece and a not infrequently nervous tension. It is a common occurrence when pal-

re breathing from a spirometer for B M R estimations fasciculation frequently appears in muscles which later show severe and sustained twitches, and it is undoubtedly increased by breathing oxygen at increased tensions. A number of subjects show facial perspiration varying in degree from fine beads to literal pouring. Generalized perspiration is infrequent, and is usually associated with the occurrence of more acute symptoms. Salivation seems to be increased (as in animals), but some is undoubtedly reflex from the irritation of the mouthpiece, and is therefore difficult to assess. Almost all the subjects appear to be under stress even though they have no specific symptoms. These are all early findings, and the subject will continue without further event for varying times according to his tolerance.

The next group of symptoms to be described may be classified as minor crises in so far as they are usually transient and the subject is able to continue breathing oxygen. The subject may complain of nausea, vertigo, malaise, apprehension, or choking sensations. Intermittent p-twitching of a slight or moderate degree or an increase in the frequency of respiration may be noted by the observer. Palpitations, involving an awareness not only of the action of the heart but of arterial pulsation throughout the body, may cause the subject considerable discomfort. These disturbances may last for only a few seconds to a few minutes, and the subject finally resumes his former symptomless state and may continue the exposure for a considerable time before an acute end-point. The course of these minor crises is unpredictable, and the observer has to be constantly on the alert for a sudden exacerbation with danger of convulsion. Other subjects have no such transient episodes, but first experience pronounced symptoms shortly before or at the end-point.

Finally, a group of symptoms occur which, although not demanding immediate cessation of the exposure, signify that intoxication is becoming more intense and that acute symptoms will not be greatly delayed. There may be pronounced mood changes with depression or euphoria, severe irrational apprehension, sometimes amounting to acute terror, may be experienced. Alternatively, the subject may feel "far away" or experience complete indifference to his surroundings. Others are somnolent, and in one case the subject fell into a deep sleep from which he was aroused with difficulty. At this time the attendant may notice various abnormalities of behaviour, the subject showing clumsiness with his apparatus, loss of balanced judgment, fidgeting, or the unnatural disinterest already mentioned. A sensation of depression or constriction, frequently indescribable, in the epigastrium or in the praecordium may be experienced. Visual or auditory hallucinations are late phenomena and mean that the end point is not far off. They have only occasionally been reported in the earlier crises. Visual disturbances include flashes of light, usually in the centre of the visual fields, haloes round objects, lateral movements of images, micropsia, and apparent changes in illumination. Auditory hallucinations such as bell-ringing and knocking are far less common. Both deafness and hyperacuity are encountered. Elaborate auditory or visual hallucinations, which are classified initially under psychical seizures, are not experienced. Unpleasant tastes and odours have not been encountered (the "dry" but were reported by two subjects in the "wet"). Constriction of the visual fields occurs only after prolonged exposures, is gradual in onset, and can be marked, without the more acute manifestations of oxygen poisoning. In a few cases nausea and vertigo, together or separately, become so severe that the subject reverts to air-breathing before convulsive symptoms appear.

Definite twitching of the lips usually means that the end-point is near. This is the most common termination. The twitches are powerful and sustained. They are usually first seen on one side of the upper lip, but if the exposure continues they increase in power and frequency and spread to the whole mouth and face and sometimes to other parts of the body. On occasion a marked twitch is followed by a long period of quiescence before recurrence. This is exceptional, and in most cases, if oxygen-breathing continues, convulsive movements of the lips pass into generalized jactitations or convulsions. Twitching of the cheek and nose are often seen with or without lip-twitching. Occasionally there is isolated twitching of the arm, leg, spinal, or abdominal muscles.

In some cases a few seconds or minutes before the end of the respirations, which are normal and serene throughout, show a number of abnormalities. The commonest occurrence is rapid panting. In other instances there is marked inspiratory predominance, reminiscent of asthma, but without wheezing. Respirations sometimes become grunting in character, and in severe cases this may develop into an acute state of apnoea in the inspiratory position. Subjects with severe respiratory symptoms usually convulse, although a few escape on being turned on to air.

It will be seen that an accurate description of such a varying picture is not easy. The clinical impression gained was of two distinct processes occurring in many different patterns. One is an insidious intoxication which may affect the function of practically any part of the central nervous system, and added to this is an increasing convulsant tendency that is usually, but not always, first manifested in the facial muscles and finally becomes generalized. There are great variations in the resistance to the general background of intoxication and in the resistance to the convulsant factor. Certain individuals may show powerful twitching movements, either localized or generalized but retain consciousness, while others pass into what is indistinguishable from an epileptic fit immediately after such convulsive movements and sometimes in their complete absence.

The syncopal type of attack was seen on only a few occasions. There were usually associated muscular twitchings. One of these subjects appeared like a case of so-called "shock," being pale, flaccid, and in a cold sweat, with a poor pulse. He did not convulse. The blood pressure was not ascertained. Another subject collapsed but did not appear to be "shocked." He was unable to move or speak, although he appreciated his surroundings. Such states are described in epilepsy under the name of cataplexy. Space does not allow the description of individual exposures.

Convulsive Attacks

The convulsive attacks of oxygen poisoning were on the average of two minutes' duration, the subject being unconscious. If the subject was turned on to air immediately the convulsion started only one attack resulted. In one case where oxygen breathing was inadvertently continued a second convulsion began after a pause of about thirty seconds. Incontinence occurred in a number of instances. Detailed description of these attacks is unnecessary as they in no way differed from a major convulsive attack of idiopathic epilepsy.

Confusion, dissociation, headache, nausea, and vomiting as experienced after an epileptic fit occurred in many cases. Some individuals showed marked emotional instability, which is not a feature of leptazol or electrically induced post-convulsive states. The majority, however,

were subdued and ataxic for about 15 minutes after, and if left alone fell asleep. Occasionally subjects complained of pronounced photophobia. In a number of cases there was post-convulsive automatism, the subject suffering from complete amnesia for a period from one-half to seven hours. There were some stiff backs and subcutaneous extravasation due to muscular violence.

Off-effect

A number of subjects suffered marked exacerbation of symptoms after returning to air-breathing. Severe nausea, increasing pallor, sweating, and vertigo have all occurred in subjects who were previously symptomless. Other subjects showed a sudden dissociation and panting. In a few cases it appeared that convulsions were precipitated by reverting to air-breathing. A possible explanation of this off-effect may be the sudden fall in oxygen tension, causing temporary cessation of respiration in already damaged nerve cells. In some cases, no doubt, the toxæmia was already of such a degree that convulsions were inevitable. Decompression appears to precipitate convulsions in such subjects and also in animals. The "startle" phenomenon, where sudden and unusual sensory stimuli precipitate convulsions—that is, decompression—may account for some of these cases*. It has therefore become a rule in this work that if a subject has severe symptoms and reverts to air-breathing he is not decompressed until his symptoms have gone and relative normality has been attained.

The recovery from a non-convulsant end-point is remarkably rapid and the subject appears normal in five minutes or less. All twitching usually disappears in about a minute. The subject may appear dazed for a few minutes longer and his respirations are inclined to be irregular, with intermittent deep excursions. Euphoria is frequent, but this may well be due to relief at having survived a toxic exposure without convulsing. In some cases pallor persists for as long as an hour, and sometimes the subject behaves as if he were slightly drunk for the same period. This latter syndrome is known in experimental diving circles as "oxygen jag".

Oxygen Poisoning under Water

So far only signs and symptoms as seen in the "dry" have been described. In a series of 388 dives to end-point, under water, the following symptoms were recorded: convulsions in 46 (9.2%) cases, twitching of lips, 303 (60.6%), vertigo, 44 (8.8%), nausea, 43 (8.3%), respiratory disturbances, 19 (3.8%), twitching of parts other than lips, 16 (3.2%), sensations of abnormality (drowsiness, numbness, confusion, etc.), 16 (3.2%), visual disturbances, 5 (1%), acoustic hallucinations, 3 (0.6%), paraesthesiae, 2 (0.4%). The most striking observation is the remarkable predominance of lip-twitching. It is probable that many of the more subtle symptoms occurred but that they were difficult to appreciate under water. A number of divers who reported severe lip-twitching, and were hauled up jactitating and confused but did not convulse, remembered only severe lip-twitching as their end-point. Further observations by the attendant at such a critical time were difficult, particularly with the subject in a diving-suit.

Since Bornstein's single experiment in the "dry" (1912) it has often been stated that exercise at toxic tensions caused twitching of the muscles employed. In a series of "wet" dives to toxic depths with hard work symptoms were analysed in 120 end-points. The findings were as follows: Convulsed, 6.8%, lip-twitching, 50%, vertigo,

20.8%, nausea (vomiting two cases), 17.5%, choking sensations, 2.5%, dyspnoea, 2.5%, body tremors, 1.7%.

It appears that nausea and vertigo increase in frequency if the subject is exercising. Twitching of the muscles exercised was not encountered in the whole series. Carbon dioxide absorption has to be extremely efficient with hard work, especially in air, where the canister becomes hot, and a large series of such experiments in the "dry" were marred by inadequate carbon dioxide absorption, are not reported here. In these "spoiled" experiments the subjects experienced twitching of muscles and severe tremors, and this was shown to be due to high tensions of carbon dioxide in the circuit.

Subjects breathing oxygen at increased tensions but without toxic signs or symptoms occur are remarkably normal. The mental torpidity described by some observers has not been noted, even at considerable depths, except after long exposures in the "dry". Judgment and the capacity for hard physical work appear to be in no way impaired. Under-water divers are more free of symptoms than are in the "dry" right up to the moment of lip twitching or convulsing. No doubt the abnormal environment and accoutrement obscure the minor premonitory signs. This apparent normality and the frequent suddenness of convulsive symptoms make oxygen-breathing under water at toxic depths highly dangerous, particularly as the subject often gains a very false sense of security.

Special Investigations

These experiments were carried out under war conditions, and owing to the urgency of the work and the many other immediate operational problems being investigated it was unfortunately not possible to extract the maximum data from this unique series by elaborate special investigations. However, a number of important observations were made, and these will now be considered under appropriate headings.

"Lorrain Smith Effect" (Pulmonary Damage) in the Human

Lorrain Smith (1899) reported fatal pneumonia in a rat at four days' exposure to 73% oxygen. Many animal experiments have been carried out since, and the general conclusion has been that 60% oxygen causes no pulmonary damage in animals or man (Barach, 1926) even after indefinitely prolonged exposures. Becker-Freyseng and Clamann (1939) produced bronchopneumonia in a healthy man by breathing 90% oxygen for 60 hours.

In over 1000 experiments where subjects were exposed to toxic pressure (4.68–1.9 atms abs) the exposure was always terminated owing to signs or symptoms involving the central nervous system. Frequent chest examinations were completely negative. At more shallow depths, however, nervous symptoms are encountered only after very long exposures or not at all. It was thought possible that there might be a greater risk of lung damage at such depths. Dives up to three hours at 2.1 atms abs in the "wet" caused pulmonary irritation. A series of prolonged dives to 12 (3.7 m, 1.36 atms abs) with periods at 50 ft (15.2 m, 2.5 atms abs) gave equally negative results. An example was a dive of 6 hours 9 minutes, continuously in oxygen at 12 ft (5.39 minutes) and at 50 ft (30 minutes), where no pulmonary irritation was encountered.

It can be stated with reasonable certainty that no real water dive will be made where lung damage will result at high tensions of oxygen, and that at depths greater than 30 (9.2 m) nervous symptoms will terminate the dive long before any pulmonary irritation occurs. Lorrain Smith (1899) reported that a rat died of pulmonary damage after 20 minutes at 4.5 atms of oxygen, yet a subject completed 61 minutes at 4.6 atms, breathing oxygen, with no demonstrable pulmonary damage. Total evidence suggests that man has more tolerance to lung damage than small experimental animals.

* Since writing this article it has been noted that a similar suggestion was made by J. W. Bean (1945).

A number of these subjects breathed oxygen at increased tensions several times a week for two years. It was considered possible that although the pulmonary damage suffered in a single exposure was inappreciable there might be a cumulative effect. Frequent routine examinations of the subjects' chests were therefore carried out. Radiographs were taken regularly and the vital capacities noted. In not a single case has there been any positive finding suggestive of lung damage. The subject who dived to 70 ft (21.3 m) to end point two or three times a week for three months won the Portsmouth middle-weight boxing championship during this period. It would appear that there is no cumulative effect on the lungs in oxygen diving.

Cardiovascular Findings

Benedict and Higgins (1911) reported bradycardia in man breathing increased percentages of oxygen at atmospheric pressure. This finding has often been confirmed, both in man and in animals. Bean and Rottschäfer (1938) showed with animals that, although the bradycardia was mediated by the vagus, blocking of this nerve had no effect on oxygen poisoning. In the experiments described here it was found that, although the pulse changes were little more than could be accounted for by prolonged basal conditions, there was in some cases a marked slowing of the pulse (35–50), particularly after long exposures at 60 ft (18.3 m). The pulse was regular and there was no suggestion of dropped beat or any type of heart-block. Some of these subjects who did not convulse did not recover their normal rate till several hours after the exposure. The degree and rate of onset of the bradycardia had no fixed relation to tolerance or other symptoms, nor did the pulse changes give any warning of acute symptoms or convulsions.

Only a limited number of blood-pressure recordings were made at 90 ft (27.4 m). There was a gradual rise of both systolic and diastolic pressures which stabilized after some 10 minutes at about 15 mm above the normal levels. Just before the onset of acute symptoms a further brisk rise of about 15–20 mm occurred. These findings are similar to those of Behnke *et al.* (1935–6). Microscopical study of the subjects' nail-bed capillaries while under toxic tensions and while suffering acute symptoms revealed no significant changes. X-ray and clinical examinations have shown no enlargement of the heart in subjects who were often exposed to toxic tensions over a long period. It is difficult to see why this should occur unless there is severe pulmonary damage, but it is a common belief among medical officers and divers, particularly in the Italian Navy, that oxygen breathing increases the size of the heart. This has not been confirmed.

Neurological Findings

In experiments continued over a period of three years no adverse after-effect has been noted in any subjects' neurological integrity, intellectual ability or personality. Neurological examination of subjects while breathing oxygen at 60 ft (18.2 m) and 90 ft (27.4 m) in the 'dry' showed no significant change in reflex activity. Constriction of the visual field has already been mentioned. Some subjects showed marked dilatation of the pupils as they approached the end of the exposure. The only other important finding was the development of a positive Chvostek sign in a number of subjects during exposures. Although this usually developed in the latter half of the exposure, it was not a reliable sign of the approach of acute symptoms although if present it became more marked as the exposure continued. Some subjects had a positive Chvostek sign at any time. Controls in air at atmospheric pressure revealed that a few otherwise normal subjects had a positive Chvostek sign, which in some cases was present only and absent on another. Such a finding in air, or even developing during the exposure, did not necessarily signify poor oxygen tolerance. In one quite unique subject acute symptoms were started with twitching of the muscles of the left hand (the only case of twitching of the hand recorded in the whole series), which then spread up the arm to the shoulder and on a few occasions this was followed by convulsions. This series of events was similar to a Jacksonian attack and quite unlike the usual muscular twitching.

Electro-encephalographical Findings*

Briefly, exposure to oxygen at 120 ft. (36.6 m) had no immediate effect on the EEG recordings. In general there was a slight increase of fast activity (25–32 p/s) and also increase in voltage of the 3–5 p/s waves. Coupled with this was a progressive decrease of the amount and voltage of the dominant frequencies (6–12 p/s). The tracings tended towards a sequence of 3–5 p/s waves with a superimposed ripple of fast activity. These abnormalities were episodic. Infrequently, spikes—that is, single high-voltage fast sine waves—appeared and increased in number. They were bilateral and symmetrical. Subjects who had non convulsant end points showed no other changes. Those who convulsed gave a picture of electrical activity during and after the fit which was indistinguishable from that seen in grand mal epilepsy. It was apparent that there was nothing specific in the convulsions of oxygen-poisoning, as regards electrical activity, once they had started. In some cases there were signs of disturbance—that is short bursts of 5 p/s activity with increasing voltage just before the attack. Others showed no change of cortical electrical activity before the major convulsive attack. In view of the similarity of the convulsions, both clinically and electrically to those of epilepsy it was thought that a study of the EEG of subjects in air, and with hyperventilation, might show inborn instabilities that could be correlated with oxygen tolerance. Fifteen subjects from the Admiralty Experimental Diving Unit were graded in order of average oxygen tolerance. This was based on many dives at various depths in the 'wet' and in the 'dry' over a long period. There was no statistically significant correlation, although the three most resistant subjects had normal EEGs. However, the other two 'normals' occurred in the last five in the endurance rating. No 'normals' had convulsed at this time, but two did so in the later experiments.

Electromyographs of the lower facial muscles showed bursts of potential with lip twitching without any associated abnormality of cortical electrical activity. Conversely, bursts of fast cortical activity occurred without increase in muscle action potential. Observations showed that clonic movements or twitching of peripheral muscles was not necessarily associated with changes in the EEG.

Toxic Effects of Oxygen on Brain Metabolism

Prof F Dickens (1946) in associated MRC (R.N.P.R.C.) research, investigated the action of high pressure oxygen on rat-brain slices. This work is briefly referred to here for the sake of completeness. He showed that the respiration of isolated cerebral cortical tissue is progressively and irreversibly poisoned. Curves plotting the percentage fall of initial respiratory rate against time were remarkably similar in type to those showing the elimination of a group of individuals by toxic symptoms at a fixed depth (see Fig 4 'dry'). The time/pressure relationship for a fixed degree of respiratory poisoning was also of a similar type to that obtained for the means of times causing acute symptoms in a group of men at various depths. The order of sensitivity to high pressures of oxygen of the various rat tissues was as follows: Brain cortex > spinal cord > liver > testes > kidney > lung > muscles. The actual tension of oxygen in the brain tissue *in vivo* and *in vitro* under these conditions is not yet accurately known, but from Dickens's experiments it is certain that convulsions occur in man and animals when the brain tissue respiration is but minutely impaired. A similar problem is presented by the effect of narcotics on brain slices and *in vivo* (Quastel, 1939). Dickens presents strong evidence that the primary effect may be in the inhibition of pyruvic oxidase, and that the secondary effects would be general poisoning of carbohydrate oxidation, since all known paths of carbohydrate oxidation converge at the stage of pyruvate. Magnesium, manganese, and cobalt ions strongly protect pyruvic oxidase from oxygen poisoning in tissue slices. Protection by metallic ions is not entirely similar *in vivo* in animal experiments (Marks, 1944). In view of the known -SH character of this enzyme and the known ability of these metals to protect this group, it is likely that

* These unpublished EEG investigations were carried out in the later collateral MRC (R.N.P.R.C.) research by Brown, Downman, MacIntosh, and Williams. The unit subjects were employed in a number of the experiments.

the -SH group of pyruvic oxidase is the seat of oxygen poisoning. The irreversibility of the poisoning in these experiments may be explained by the known difficulty of reconstituting the -SH group *in vitro*. If, as it appears, convulsions or acute symptoms occur in a very early stage of this process, then reactivation in the more physiological conditions of the intact organism is extremely feasible. This would account for the reversibility of acute oxygen poisoning in man and animals if the exposure is immediately discontinued.

Discussion

The most important aspect of oxygen poisoning is the intoxication of the central nervous system. It seems that the whole cerebrospinal axis is involved. The twitching of the muscles is definitely subcortical in origin, and the sensitivity of the facial nerve to tapping would indicate that even the most peripheral components are affected. Meanwhile the cortex is also being poisoned, and in a number of cases phenomena exactly similar to epileptic auras occur which are presumably due to cortical dysfunction. In some cases severe muscle-twitching, and even convulsions, may be precipitated without any such aura being reported. The more peripheral motor discharges may predominate throughout and even cause generalized jactitations without electrical or clinical evidence of cortical disturbance. In other cases non-convulsant cortical disturbances may cause symptoms of such severity that the exposure is discontinued. The remarkable individual variation in reaction to unphysiological tensions of oxygen is again emphasized.

It is not known why the lips should be so specifically affected. The possibility of the added irritation and fatigue caused by the mouthpiece was considered, but was excluded by the demonstration of lip-twitching in man in helmets without mouthpieces (Donald, 1942), and also in rabbits and other animals (Marks, 1944). These peripheral twitching movements are almost certainly related to the myoclonic seizures of epilepsy, in contrast to the Jacksonian type of attack. These myoclonic seizures commonly affect the face, but can occur elsewhere. Penfield and Erickson (1941) concluded from electroencephalographic studies that these attacks originate from the grey matter in the brain stem and spinal cord. It is significant that a similar conclusion has been reached with regard to the origin of the muscular twitching in this work. Of equal interest is the comparative rarity of myoclonic seizures and frequency of Jacksonian seizures in epilepsy, and the reverse in oxygen poisoning. The rarity of somato-sensory disturbances (paraesthesiae) and elaborate hallucinations (perhaps associated with absence of petit mal) is worthy of note. At no time was any attack akin to petit mal observed either clinically or electrically. Thus even in oxygen poisoning, in which epileptic auras are closely imitated, petit mal is unknown. This emphasizes the uniqueness and importance of that phenomenon in idiopathic epilepsy.

A small group of naval epileptics (five) tested by the MRC workers did not show any apparent increase of sensitivity to oxygen poisoning, but the experiments were too few for definite conclusions to be drawn. Penfield emphasizes the great variability in the physiological state of the epileptic cortex. "It may be quite normal in reaction, or it may be abnormally stimutable, completely refractory, or at other times unequally hyperactive." Such variability of behaviour combined with the enormous variability of human susceptibility to high pressures of oxygen makes a far larger series of experiments desirable. However, the pattern of toxic symptoms appeared similar to those in normals, and the general impression gained was that there was no essential difference of reaction, or any

increased accessibility to the convulsant mechanism, by the channels or processes involved in oxygen poisoning. It is possible, and indeed highly probable, that there are distinct chemical or cellular systems the adequate and separate disturbance of which will allow or cause convulsions. On first principles it would appear likely that the depression of essential carbohydrate oxidation in nerve cells would cause depression in function and not increased activity. If this is the case, then the "auras," motor twitches, and convulsions are more likely to be release phenomena and not due to primary excitability of the parts of the central nervous system concerned. The sudden violent discharge to utter exhaustion (as shown in convulsions by the EEG) is strange behaviour in cells in which the oxidative processes are damaged.

The relatively slow and deliberate evolution of auras akin to those experienced in epilepsy is, so far as I know, unique to oxygen poisoning and should be further explored by experimental workers. Although the condition is artificially produced, it approximates far more closely to the natural epileptic phenomenon than other induced convulsant states. The electrical localization of epileptic discharges in idiopathic non-convulsant equivalents has already been carried out in a number of cases. It would be possible to select resistant subjects who experienced definite auras without marked "peripheral" motor discharges. The electrical study of these auras in such subjects would be a new approach to the problems of cortical localization and function. Further study of the various patterns of cortical dysrhythmias before convulsions may contribute to the knowledge of the mechanisms of epilepsy.

The therapeutic use of oxygen as a convulsant in the various psychoses has been suggested in the past, but the lack of knowledge of the syndrome, combined with the greater ease and safety of other methods, has so far prevented its use for this purpose. The complicated and rather frightening ritual (to strangers) of pressure work, and breathing from a closed circuit, render the value of this method very questionable. Changes in the central nervous system could be induced up to the point of convulsions. With experienced attendants these could be avoided in most cases if desired. Evidence may be obtained as to whether the improvement, if any, was caused by such changes alone or by the convulsions they can precipitate.

Conclusions

In the first large series of experiments on human beings, knowledge of the dangers and symptoms of oxygen poisoning has been expanded. It has been demonstrated that these dangers are far greater than was previously realized. The variation of tolerance between individuals, the variation of tolerance of each individual, the impairment of tolerance with work and under water, all make diving or pure oxygen below 25 ft (7.6 m) of sea-water a hazardous gamble. The impairment of tolerance under water is as mysterious as it is unfortunate. Despite the fact that a comprehensive picture of human symptoms of oxygen poisoning is now available, it is emphasized that no signs or symptoms can be given that would ensure a timely cessation of oxygen-breathing in all cases. The variation of symptoms even in the same individual, and at times their complete absence before convulsions, constitute grave menace to the independent oxygen-diver. The only possible conclusion is that such tensions of oxygen should be scrupulously avoided.

Summary

Previous research into the effect of increased tensions of oxygen on man up to the commencement of this work briefly described

An account is given of experiments to determine the tolerance of groups of men to such tensions of oxygen under varying conditions

The signs and symptoms of oxygen poisoning in man are described

The possibility of pulmonary damage by increased tensions of oxygen is discussed

Electrical and chemical changes in the central nervous system are briefly described

The relation of oxygen poisoning to epilepsy and the possibilities of further useful investigations are discussed

The danger of breathing oxygen at increased tensions is emphasized

Acknowledgments

Grateful acknowledgment is made to Flag Officer H M Submarines, Director Torpedoes and Mines Medical Director General, and Director Naval Intelligence, Royal Navy, for permission to publish this work. I am especially grateful to the M R C workers for their permission to mention some of their later collateral investigations (some of which are unpublished), thus allowing a more comprehensive description and discussion of the syndrome

I should like to thank Sir Robert Davis and Mr W Gorman Davis, of Siebe Gorman and Co, Ltd, for their help and advice

Thanks are also due to Cmdr W O Shelford, R N, superintendent of diving, for constant co-operation to Prof J B S Haldane for advice and for his and Dr H Haldane's statistical opinions to Surg Lieut Cmdr W M Davidson R N, for help in the work series, and to all members of the underwater physiology subcommittee of the Royal Naval Personnel Research Committee for valuable advice in the later stages of this work. I should like to thank the unit staff themselves particularly Mr E Crouch, Mr P Higgins, diving gunners, R N, Miss Nixon, Supt V A D, Miss Byrne, V A D, secretaries, and Miss Henderson, head V A D unit analyst. Lastly, but the most important of all, I would like to thank my experimental divers, who were all volunteers

ACUTE NON-SPECIFIC DIARRHOEA AND DYSENTERY

LOCAL CHILLING OF THE ABDOMEN AS A CAUSATIVE FACTOR

BY

G R. KERSHAW, M A, M R C S, L R C P

Acute enteritis of unknown origin is common in Europeans visiting and living in hot climates. It is so common and so widespread that the lay public in every country use a colloquialism peculiar to their district to describe the local manifestation of a complaint which, though second only to sea-sickness in its power of temporary prostration, seldom lasts more than a few days, so that it is soon forgotten or is accepted as a perennial part of the white man's burden. Its social and economic consequences, though brief, are severe to the individual, but its military consequences can be disastrous to a community of fighting men: apart from jeopardizing a single operation there is nothing so calculated to lower morale as recurrent attacks of diarrhoea.

In the intervals it is made light of by the public and is rarely considered seriously by the profession. Not all standard textbooks or monographs even refer to it, and in those that do so it is seldom discussed at a length which suggests that it is probably the illness encountered most commonly among the white population in hot climates. Even the most reputable authors, moreover, show little confidence, agreement, or justification in describing its cause, and still less in recommending prophylactic measures. It is ascribed variously to "exposure to chill, and irritation of the bowel by coarse and unsuitable food" (MacArthur, 1942), to potentially pathogenic bacteria (McDonagh, 1942), to "the recognized dysentery organisms, precipitated by sudden chilling" (Napier, 1946), and as "probably bacterial in origin" (Manson-Bahr, 1945). Macgregor (1946) gives good reasons for this dissatisfaction with the traditional causes and, after showing a close association in time with acute upper respiratory disease, favours a virus infection, on the principles believed by Burns and Gunn (1944) to cause diarrhoea in infants, as described in a *BMJ* editorial (1942).

Opinion is, therefore, overwhelmingly in favour of infection, and this belief is based on three main points: (1) Its symptomatology is similar to that due to known pathogens. (2) It occurs in outbreaks as well as sporadically. (3) In the many outbreaks of enteritis of unknown cause during the war it has been shown that the more thorough the investigation the more often is a known pathogen recovered (Hardy and Watt, 1945). Similar symptomatology, however, is known to occur with any form of irritation within the lumen of the gut, and its simultaneous appearance in different people is by no means necessarily indicative of infection, while to attribute the disease to an unknown organism which has never been demonstrated is to admit to a degree of professional complacency which is as astonishing as it is unscientific.

Chilling of the Abdomen

Perhaps equally unscientific, but of longer duration, is its traditional association with chill. In some (MacArthur, 1942, Napier, 1946) references to acute enteritis exposure to chill, in quite general terms, is mentioned as a probable factor in its cause, either predisposing or actual. This appears to have passed from one book to another without much consideration or justification. Now it is in fact a matter of common knowledge that *chilling of the abdomen* by the rapid ingestion of cold fluid in large quantities when the body is hot does often induce diarrhoea, and it is fairly

The British Legion Unit of Rheumatology set up experimentally by the British Legion a year ago, to specialize in the treatment of servicemen and women suffering from rheumatic diseases has now been transferred complete with staff from the Three Counties Hospital Arlesey Beds to the North West Hospital Havestock Hill London, N W 1. The Minister of Health has agreed to take over the unit on May 31, and to encourage the provision of further units throughout the country.

well recognized that *chilling of the anterior abdominal wall* frequently does likewise. Too much ice cream or too long an iced drink, or moderate amounts of either taken quickly instead of by sips, are methods of provoking diarrhoea as proverbial as that of allowing a wet bathing costume to "dry on" while sun-bathing. Bampffield (1819) wrote as follows:

The copious perspiration of the newly arrived European becomes accumulated, when he is sitting or walking on the lower part of the shirt, more especially about that part of the abdomen where the waistband of the small clothes or pantaloons presses against it the tight or close application of which occasions an increase of heat and of perspiration at this particular part, during the day, and intercepts the exhalation as it flows down the body, hence, if he should lie down in this state, cold will be induced on a particular part of the abdomen, by the evaporation of the exhaled fluid from the wet linen in contact with it, perspiration before profuse, will be now effectually suppressed and its injurious consequences felt by the chylipoietic viscera.

Johnson and Martin (1841) introduce this quotation to their readers by saying "We do not recollect that the following circumstance has ever been noticed heretofore as a predisposing cause of dysentery." McDowall (1927) writes:

'The wearing of so-called cholera belts signifies the importance of keeping this particular region of the body (the abdomen) warm, for the alimentary canal is a region especially liable to be infected as a result of cold. The production of diarrhoea or the return of symptoms after an attack of dysentery, which may follow a cold bath or sea-bathing has long been recognized.'

Hunt to Travellers (1938) states that "A drop in the night temperature in the Tropics constitutes another danger, so protect the abdomen with warm clothing at night time," and it advises the traveller to "consider also the liability to chill, and whether the often derided cholera belt is essential." Napier (1946) writes:

"The flannel cholera belt, whose powers of cholera prevention were of course mythical but which could be guaranteed to produce a nice band of prickly heat in most climates, has fortunately gone out of fashion. Quiescent abdominal infections are sometimes stimulated into activity by local chilling which the cholera belt was designed to obviate, it is therefore advisable for those subject to attacks of diarrhoea to put wraps round their abdomens, rather than over their shoulders, when cooling off after exercise."

Physiological Deductions

Better understanding of physics and physiology enables the present-day physician to appreciate that, owing to the high latent heat of steam, the anterior abdominal wall is seldom more chilled than by the evaporation of sweat, and also that as the temperature of the air rises so does the proportion of body heat lost by evaporation, to the eventual exclusion of other methods. He can furthermore predict other factors which will influence this process—namely, the humidity of the air and the velocity of air movement.

Diarrhoea is therefore to be expected in those entering a hot climate from a cold one, whose thinner clothes afford less protection from the cool evening breeze to an abdomen accustomed to thicker and warmer clothes, whose garments in the heat of the day cling to the abdominal wall, where they lie closest to the body, and provide a system whereby the greater the temperature the more body heat shall be lost through this vulnerable surface. It is to be expected that residents in hot climates should suffer frequently from diarrhoea while they are continually exposed to the same conditions, that the frequency of attacks should be highest in the early months of summer (Northern Hemisphere),

when the diurnal variation in temperature is greatest, and in the autumn or rainy season, when a higher humidity causes the body surface to be covered with a film of perspiration at moderate or similarly varying temperatures.

Clinical Observations

Too many have ample (and painful) experience that these expectations are often fulfilled, some clinical observations made in H.M. ships during the war may, however, provide more acceptable evidence than personal reminiscence. Typically the patient was awakened shortly after midnight with generalized abdominal colic and an urgent call to defaecate, vomiting was rare and tenesmus absent. In mild cases a few loose stools and waning bouts of colic saw the end of the attack by the following mudday, but in severe cases the colic persisted and the stools became watery, progressing even to mucous and blood stained, and the course lasted several days with marked prostration and anorexia and a slightly raised temperature. Spontaneous recovery was rapid and complete.

Sporadic cases were frequently observed to occur, more often in warm climates than in cold, among those working in parts of the ship where the temperature, air velocity, and humidity were highest, and in those wearing unsuitable clothing—for example, overalls without undergarments, shrunken sheepskin waistcoats, and, until recognized, a central source of cold drinking-water proved to be the cause of this complaint also in hot weather. The frequency of small and large outbreaks was remarkable and in contrast to the exceptional rarity with which known pathogens were detected upon appropriate bacteriological investigation when this could be undertaken, moreover not one corresponded epidemiologically in any way to the expected features of disease borne by water, food, insects, or droplet infection. It will be appreciated that distilled water was used nearly always, and that analysis of water from the storage tanks was rarely performed but never suggestive. Outbreaks usually started during the night, mostly through out the hotter months of the year, with a first peak in early summer and a second, and larger, peak in the "stuck" period of early autumn. Three major outbreaks were observed before landfall at the end of quick passage from England to the Eastern Mediterranean, during unaccustomed and exceptionally cold weather in Arctic waters, and on passage through the Suez Canal from South to North.

Investigations

The routine and repeated examination of patients' stools was carried out whenever facilities were available. In the course of three and a half years I recollect only one case being diagnosed by laboratory methods as a specific infection. No other significant findings were reported.

Water—It will be appreciated that the water consumed on board was nearly always distilled in the ships, but sometimes obtained from a certified source ashore. The fresh water storage tanks were cleaned and relined without any alteration in the incidence of the attacks, and two analyses of the water showed nothing suspicious in content or in comparison.

Food—Most food was stored up to three months, but not consumed after three years in the cold-store did not alter incidence, nor did the lack of fresh fruit and vegetables during a period of some months. Tinned food was mostly uncracked and some tins were badly dented, but blown or doubtful or were discarded. Attacks of enteritis were not associated with any particular foodstuffs, and those who had had their even meal ashore were equally affected.

Food preparation and handling—No history of intestinal infection was obtained from the cooks, and they were from time to time victims of the outbreaks themselves. Food was prepared centrally, in one large galley, and in small ones contained in a separate compartment, if

prepared for immediate use only. The temperature of the water used for the washing of cooking and eating utensils was always over 130° F (55° C) and usually very much hotter.

Droplet infection and insect vectors—The incidence of attacks was not associated in time with that of either acute upper respiratory disease or sandfly fever. Close contact between cases was not a feature of the disease, and the incidence was not higher among the sick-berth staff who slept in the sick-bay than in others. The peaks of the attacks corresponded with the maximum prevalence of flies, but attacks occurred when flies were altogether absent, cockroaches abounded at all times in the galleys and pantries.

While the practice of hygiene and the limitations of investigation by operational conditions were open to criticism, conditions were sufficiently sterile, metaphorically if not bacteriologically, to warrant attention being turned to chilling of the abdomen as a possible factor in causation. In fact the association was noticed early and the more often it was sought the more frequently it was found, until in the explosive outbreaks it was observed so constantly that it was established beyond doubt. It has been said that attacks began typically soon after midnight and affected those who ate their evening meal ashore or those joining ship in the afternoon as frequently as those whose shore leave had been stopped for many days. The only common factors remaining were the cool of the evening and the first few hours of sleep; the majority of ratings slept in hammocks, and hammocks were slung from the deckhead—the very place where the cool night air was introduced into all living spaces below deck by an extensive plenum system of ventilation.

Plenum Ventilation in Ships

This extreme frequency in ships was generally attributed to the plenum system of ventilation. The overcrowding of troopships was a notorious necessity, and in one warship in which many of these observations were made Sir Sheldon Dudley's (1946) appreciation of the spatial restrictions was by no means an overestimate, for in many compartments both the space per man and the number of air changes were half those intended at the very times they should have been liberal. The dry-bulb temperature of a forward mess deck when unoccupied, in one ship, was observed to be 90° F (33° C) in November evenings in the Western Mediterranean and in another ship to be constantly between 90° and 110° F (43° C) in a cabin amidships during four summer months in two consecutive years. In consequence working or resting in comfort was possible in some instances only so long as the louvre was pointing towards the body, the anterior surface giving the greatest relief, while at night, with blackout restrictions added, a few hours' rest was achieved only by lying (often with overalls rolled down to the waist) within a few feet of the louvre—a unique arrangement, since hammocks must be slung from the deckhead of living-spaces, where the plenum apparatus is properly spaced to avoid this very same effect by day. Ratings continued, even after being advised against it, to sleep wearing overalls rolled down to the waist with no other covering, and in cabins it was a common practice to direct the flow of air to the bunk by tying pyjama trousers to the louvre. In the explosive outbreaks the ratings who slept in hammocks suffered much more frequently, more severely, and earlier than those who slept on camp beds. It is pertinent to add here that in the previously mentioned outbreak in Arctic waters one victim was an officer, keeping a night watch in an exposed position, who was wearing a very shrunken sheepskin waistcoat.

The presentation of these few clinical observations in logical sequence may carry conviction that chilling of the abdomen or anterior abdominal wall is a common cause of acute non-specific enteritis ashore and afloat in all climates, but especially hot ones.

Prophylactic Measures

Whether it is the predisposing or actual cause is for practical purposes unimportant in the present state of medical knowledge, for prophylactic measures against this disease are not only common sense but calculable. On entering a hot climate suddenly, which air travel will render more frequent in future, the change from thick to thin clothes should be made gradually, if possible, and an under-vest worn and exercise avoided until acclimatization is achieved. During residence a bush-shirt, or a loose-fitting shirt with cellular undervest, should be worn, and a change to thicker clothes, if at all possible, made before sundown. An undervest should be worn, especially in spring and autumn and in windy or humid weather. Cool drinks should be sipped slowly by day, and sitting in the direct draught of forced ventilation for long periods should be avoided.

The plenum system as arranged in living spaces for day-time usage is unsuitable for the ventilation of sleeping accommodation where hammocks or tier bunks are employed. By night a cholera belt or a blanket folded across the abdomen should be worn with or without other bedclothes.

Whatever the mechanism of the predisposing cause opinion is still overwhelmingly in favour of infection being the actual cause. The obstinacy with which this belief is held without any basis in fact amounts to bigotry, until such an organism is demonstrated it would be at least reasonable to attribute the enteritis to a change in the ecology of the intestinal tract, which might fairly be presumed to be a sequel to vascular reflexes stimulated by chilling, but there is as yet, I believe, no evidence to show that it is not attributable to either neuromuscular reflexes or even purely physical causes such as chilling or salt deficiency (Stenning, 1945). Since it is evident that no further progress is likely from clinical observations there is here a strong case for experimental research.

Summary

Acute non-specific enteritis is common in hot climates. Its social and military consequences are important.

Its cause is subject to dispute, and prophylaxis is uncertain.

Local chilling of the abdomen is a known cause of diarrhoea. Circumstances causing local chilling are common still more common in hot climates, and extreme in overcrowded ships. Examples attributed to this cause are given.

Prophylactic measures are deduced.

A plea is made for experimental research.

EPIDEMIC DIARRHOEA AND VOMITING

BY

E. R. HARGREAVES, MB., BCh, DPH

Two small outbreaks of epidemic diarrhoea and vomiting which occurred in Cornwall during 1946 are described below, they supply presumptive evidence of the incubation period and mode of spread of the disease, and, further, that given favourable soil the condition can prove fatal. A review of the literature is included in an attempt to analyse the similarities and differences between "epidemic nausea and vomiting," "epidemic diarrhoea and vomiting," and "endemic diarrhoea and vomiting of newborn babies."

Observations

A mild form of diarrhoea and vomiting had been endemic in Cornwall throughout 1946, the first cases were noted in March, the disease reaching a peak in May and again in October. The first of these two epidemics broke out at the Redruth Public Assistance Institution in early June. The hospital block in which most of the cases occurred is a two-storied building standing alone. The top floor contains a ward for female bed-patients (A), a small ward for sick children (B), one for male bed-patients (C), and the nurses' kitchen and dining-rooms, the ground floor has wards for male (E) and female (D) up-patients. The children's nursery (F) and a ward for low-grade mental defectives (G) are in separate blocks, both a considerable distance from the hospital.

All the food in the institution, except that for the nurses, is prepared in a central cookhouse, which has been modernized and is in every way satisfactory, none of the six girls employed in the preparation of the food at any time suffered from diarrhoea or vomiting. The cookhouse for the nursing staff is on the top floor of the hospital block. A cook and a maid are employed, the maid being off duty with diarrhoea and vomiting from June 10 to 13. The water supply (mains) and the milk supply (accredited) were both investigated, with negative results.

The first case occurred on May 31 in Ward A, the subsequent 32 cases and the dates of their appearance are shown in Table I.

TABLE I—Cases at Redruth

Ward	No of Cases	Population at Risk	Attack Rate	Date of Occurrence
A Women bed patients	7	14	50%	May 31 June 3 6, 6 8 11 13
B Sick children	—	6	—	—
C Men bed patients	5	14	35%	June 1 1, 1 3 6
D Women up patients	—	30	—	—
E Men up patients	1	30	3%	June 13
F Children's nursery	—	12	—	—
G Mental patients	8	24	33%	June 10 10 11 11 14 14 15 15
H Nursing staff	9	12	75%	June 7 7 10 12, 12 15 15 15 17
I Domestic workers	3	—	—	June 7 10 14

It will be noted that the sick children's ward escaped infection in spite of its position between the two wards most seriously involved, that in each ward the interval between cases was approximately 72 hours, and that the mental ward was the only part of the institution other than the hospital block to be affected. A domestic worker who was employed in Ward A but slept in a side ward on the mental block developed the disease on June 7, the first case occurred among the mental patients on June 10.

Details of the clinical history of the epidemic are included in Table III. Briefly, the symptoms were mild, though diarrhoea in a few cases was prolonged and severe, definite prodromal symptoms were absent, the attack beginning with lower abdominal colic, followed within half an hour by forceful repeated vomiting. Alternatively the abdominal pain was absent, vomiting being the primary symptom and so sudden in its onset that the patient vomited over the table or bedclothes. Within a couple of hours diarrhoea supervened, with copious and frequent stools, 12 to 20 being passed in the first 24 hours. Mild pyrexia was present in 10% of cases, but with one exception the temperature was normal again within 24 hours. Relapses were not seen, but reinfection occurred in two instances after a lapse of six to eight weeks.

A second outbreak of epidemic diarrhoea and vomiting occurred during December at the County Mental Hospital, Bodmin. The hospital accommodates 1,524 patients. The epidemic was confined to the female block, a large two-story building split into four wards, each of 60 patients. The first cases occurred in Wards 1 and 3 on Dec 4, and between that date and the occurrence of the last case on Dec 12, 27 patients were affected (Table II). The clinical picture was identical with the Redruth outbreak, though owing to the high average age of the patients, manifestations were more severe, three deaths occurring from dehydration and collapse in patients, all of whom were over 75 years of age. Details of the dates of onset of disease are given in Table II.

TABLE II—Cases at Bodmin

Ward	No of Cases	Population at Risk	Attack Rate	Date of Occurrence
1 Female	17	60	28%	Dec 4 6 6 7 7 7 9 9 9 10 10 12 12, 12 12 12
2	Nil	60	—	—
3	10	60	16.6%	Dec 5 5 6 6 6 9 9 9 9 12
4	Nil	60	—	—

The hygiene in the institution was carefully investigated and found to be satisfactory. A central cookhouse supplies food for the hospital, the water is main supply, and the milk comes from the home farm. Samples of milk and water were taken, but results were negative. Numerous samples of stool and nasal swabs were taken from patients in both epidemics, but apart from two specimens containing Morgan's bacillus, and one from which *B. dysenteriae* (Flexner) was isolated, no pathological organisms were found. Agglutination to typhoid and salmonella groups was likewise negative.

In each epidemic routine measures for the prevention of spread of alimentary and upper respiratory tract infections were taken—namely, immediate isolation of patients, adequate ventilation and bed-spacing, and the wearing of masks by the nursing staff. Such simple measures appear to have been rewarded by very good results.

Comments and Conclusions

Perusal of the dates given in Tables I and II leads to the conclusion that the incubation period in the two outbreaks described was 72 hours, with a minimum of 48 hours and a maximum of four days. In both of the epidemics a high attack rate occurred in one or two wards, whereas adjacent wards in the same block were unaffected, in spite of the fact that all were supplied with identical food and water, further, all samples of food, milk, and water were satisfactory. One must conclude that the infection is borne and gains entry through either the upper respiratory tract or the gastro-intestinal tract—probably the latter,

signs of involvement of the fauces are not frequent. The disease attacks all ages, and usually follows a mild course though among the aged symptoms are more serious and the disease may prove fatal.

Literature and Discussion

The first recorded outbreak of epidemic nausea and vomiting in Britain occurred in 1936, when Miller and Raven (1936) described an epidemic in a girls' boarding-school in Thanet. Since this date at least four epidemics of a similar type have been recorded. In order to facilitate the comparison of the epidemiology and symptoms of these outbreaks I have tabulated the salient features (Table III).

themselves and the order of their predominance in different epidemics may be accounted for by the different age groups affected, the season of the year, and the well-known existence of closely related but slightly different strains of the organism. The endemic distribution with periodic exacerbations into mild widespread epidemics, the short incubation period, and the absence of sustained immunity strongly resemble the behaviour of the common cold or influenza, so that it seems probable that a virus will be found to be the causative organism. Reimann *et al* (1945) were unable to transmit the disease to animals or to isolate a filtrable agent, but they obtained results strongly suggesting that the disease could be communicated

Relapses	—	—	A few cases After one week	—	Nil	Nil	—	Nil
Babies affected	No	No	No	Yes	—	Yes	No	No

It will be seen that epidemics described under the headings of epidemic nausea and vomiting, acute gastro enteritis, and epidemic diarrhoea and vomiting possess many points of similarity. They have seasonal incidence in spring and autumn, an incubation period of 48 to 72 hours, and symptoms are of an afebrile gastro intestinal infection, mild in nature, lasting three or four days and attacking in the main children and young adults. With the exception of the outbreak at Bodmin, described above, no fatal cases have been reported.

It is highly probable that all these cases were caused by the same organism. The slight variations in the symptoms

to human volunteers by the inhalation of a fine mist of nasopharyngeal washings or stools from patients. The evidence that epidemic diarrhoea and vomiting of newborn babies is not caused by the same organism as that in adults is strong. Babies were involved in two of the six epidemics reviewed above. The first was an epidemic outbreak of diarrhoea and vomiting in a general hospital; the patients affected were for the most part adults, but the disease spread to two of the three babies wards, 37 mothers and 22 babies contracting the disease. In their description of the epidemic Brown *et al* (1945) state 'It was soon apparent in respect of the young babies that this outbreak

in no way resembled in severity a previous epidemic, of neonatal diarrhoea which had occurred in the maternity wards at the beginning of the year, and which had been associated with a high mortality. Moreover, on that occasion no adults had been involved. The second, described by Sakula (1943), is a typical outbreak of diarrhoea and vomiting occurring in newborn babies, with a case mortality of over 80%.

The clinical distinction between these two epidemics, both involving babies, is obvious. Further evidence against the association of the two diseases is supplied by the infant mortality rate for diarrhoea and vomiting in Cornwall. Throughout 1946 a widespread outbreak of diarrhoea and vomiting was prevalent among the adult population. Yet the infant mortality from diarrhoea and vomiting for 1946 is the lowest for some years, being 1.7 per 1,000 live births.

Summary

Two outbreaks of diarrhoea and vomiting occurring at two county institutions in Cornwall during 1946 are described. These outbreaks were part of a widespread epidemic among the surrounding population. With the exception of three deaths all in aged patients symptoms were mild and conformed to previous epidemics reported in the literature, a summary of which is included. Evidence obtained from these Cornish outbreaks points to an air-borne disease with an incubation period of 72 hours: the portal of entry being either the upper respiratory or the gastro-intestinal tract, the organism is probably a virus. The relation between epidemic diarrhoea and vomiting in adults and that which occurs in newborn babies is discussed, the evidence points to the two conditions having a separate aetiology.

FATAL POISONING BY "LETHANE" INSECTICIDE

BY

C. V. HARRISON, M.D., B.Sc.

The following case is recorded in the belief that it is the first example of fatal poisoning by lethane insecticide.

Case Report

A woman of 35 was found unconscious in a chair, breathing heavily. She had vomited and there was an empty bottle of 'semprolia' lethane insecticide near by. It was subsequently discovered that she was a widow and had been ailing with abdominal symptoms for some time and, being too ill to work, was nearly destitute. She was immediately transferred to hospital, but on arrival was found to be dead.

The relevant necropsy findings were as follows. The face was more pink than usual. The right side of the heart was dilated and the internal organs were moderately congested. The mouth and oesophagus were healthy. The stomach contained a little oily fluid with a strong odour of oil of citronella like that of the bottle found by her. There were numerous pin-point petechiae running together into clusters mainly along the lesser curvature of the stomach but spreading out on to the adjacent walls. There were similar but less severe petechiae in the duodenum. The appendix was the seat of a well-localized abscess containing approximately 5 ml of pus, this was presumably the cause of the abdominal symptoms. The liver was acutely congested and had the same odour as the stomach contents. There was an excess of frothy mucus in the trachea and

major bronchi and some oedema of the right lung. In addition both lungs showed extensive petechiae running together to form ecchymoses under the pleurae of the lower parts. All other organs appeared healthy.

Microscopically the liver contained a trace of fat and had collections of inflammatory cells in most of the portal tracts. Other organs showed no definite abnormality. The central nervous system was examined particularly for evidence of nerve cell damage, and some swelling of the cells and loss of Nissl granules was noted, especially just lateral to the fourth ventricle, but as the necropsy was carried out 16 hours after death it was not possible to be certain that these were not autolytic changes.

Comment

The empty bottle found near the patient was of 55 ml capacity. It had contained an insecticidal hair oil, the composition of which was given on the label as lethane 384 special, 49%, light petroleum, 49%, oil of citronella 2%. Lethane 384 special consists of 12.5% of lethane 384 (N-butyl carbonyl thiocyanate), 37.5% of lauryl thiocyanate, and 50% light petroleum. A 55-ml bottle would therefore contain 3.5 ml of N-butyl carbonyl thiocyanate and 10.3 ml of lauryl thiocyanate. The patient was judged to be about 8 st (50 kg), and, assuming that she took the whole contents of the bottle, the dose would be 0.07 ml/kg of lethane 384 and 0.206 ml/kg of lauryl thiocyanate.

Cameron *et al.* (1939), who studied the toxicity of these two drugs in rats, rabbits, and guinea-pigs by subcutaneous and intraperitoneal injection, found that the minimal lethal dose of lethane 384 was between 0.025 and 0.2 ml/kg and of lauryl thiocyanate between 0.08 and 10 ml/kg. In the case of both drugs, therefore, the maximum dose which could have been taken by the patient lay within the range of lethal doses observed by Cameron. In fact, the effective dose taken was less than that stated above, because some was lost by vomiting, and further, we were unable to discover whether the bottle was full. Even if the effective dose was as little as one-half of the maximum possible, the lethal dose for each drug still lies within the ranges observed by Cameron.

Cameron failed to observe any characteristic post-mortem lesions in his experimental animals, but concluded from clinical observation that death was due to respiratory failure, probably nervous in origin. We have similarly failed to find any characteristic lesion. The dilated right heart, congested viscera, and pleural petechiae suggest that death was due to respiratory failure. The petechiae in the stomach were presumably due to simple irritation, and the inflammatory changes in the liver were almost certainly secondary to the appendix abscess.

The particular preparation which proved fatal in this case can be bought at any chemist's shop and is not labelled 'poison'. It is marked with the words "For external use only" in print measuring 20 letters to the inch, followed by the words "Not to be taken" in print measuring 24 letters to the inch.

In view of the toxicity of lethane insecticide as evidenced by the present case it seems highly desirable that such preparations should be clearly labelled "Poison".

Reviews

ATLAS FOR DERMATOLOGISTS

Atlas of Histopathology of the Skin By G. H. Percival M.D., F.R.C.P. Ed. A. Murray Drennan M.D. F.R.C.P. Ed., and T. C. Dodds F.I.M.L.T. FRPS (Pp 494 376 photo micrographs in colour 75s) Edinburgh E and S Livingstone 1947

Owing to its accessibility, it is easier to make microscopical preparations to illustrate morbid conditions of the skin during the lifetime of the patient than of other bodily organs. Moreover the numerous morbid conditions that may affect the skin make possible a wide variety of microscopical pictures. A comprehensive atlas of the histology of skin diseases might therefore be an enormous undertaking were it not that the clinical picture is often more distinctive than that revealed on microscopical examination, for it is not uncommon for eruptions presenting different clinical appearances to show very similar histopathological changes.

The authors have produced a very good book. There are 370 figures, almost all in colour, the first group illustrating the normal skin and its appendages in about 20 figures, the remainder constituting a fairly complete atlas of cutaneous histopathology, and including figures of most of the important animal parasites common in the British Isles. The authors have not included any figures of the pathogenic fungi, although there are illustrations of the pathological changes which these fungi cause. This atlas a product of the Edinburgh School, illustrates British dermatology, and the authors, who have been assisted by many British dermatologists, have barely drawn upon the rich material provided by the Tropics but there are illustrations of several of the tropical skin-infesting insects and of Oriental sore and leprosy.

We may question whether colour photography is yet able to yield illustrations equal to those provided by the artist skilled with pen and brush. In this volume the colour illustrations have been made by the Finlay process, which is generally admitted to be the best method of reproducing colour photographs, and though the illustrations are as good as any we have seen, this process is yet far from perfect. It appears to accentuate the blues and purples unduly and to attenuate the reds. Most of the sections illustrated here were stained with haemalum and eosin and the Finlay process does not appear to do justice to them, in some instances giving them a muddy appearance. On the other hand the definition of those (not so numerous) prepared with iron haematoxylin and the van Gieson process is clearer, and the sections prepared to show elastic tissue are also good. One of the best illustrations—figure 20—shows nerve fibres impregnated with silver ending in a Meissner corpuscle.

The authors have accomplished a difficult task with skill. As they themselves say, this work is not intended for the general medical public but primarily for those interested in the specialty of dermatology, and every dermatologist should study it. The general pathologist, however, will find it useful in helping him to solve his occasional dermatological riddles.

H. HALDIN-DAVIS

GROUP PSYCHOTHERAPY

Group Psychotherapy: Theory and Practice By J. W. Klappman M.D. (Pp 344 21s) London William Heinemann (Medical Books) 1946

During the war the necessity of treating large numbers of patients suffering from not very deep-seated psychoneuroses led to renewed attempts to practise group therapy. This had been tried in the 1914-18 war but fell into disuse with the insistence on complete analysis and catharsis of each patient. The author of this book surveys the subject of group psychotherapy and suggests that too much stress may have been laid on the patient's emotions and that much can be done by encouraging him to use his intelligence. Moreover in group therapy a transference may be obtained to both the therapist and other members of the group, causing an extraverted attitude in the patient, which often arouses his interest and makes him desire

individual therapy when that is necessary (as it generally is) in addition to group therapy.

Lectures can teach the patient the nature of his illness and discussion by the group of anonymous case histories often of members of the group, may give him some insight into his own condition. These methods are suitable for treating groups of mild schizophrenics in mental hospitals, and groups of patients with other types of mental illness out-patients or even private patients, may be organized. Some authorities favour set lectures others discussions, psychodrama, or puppetry, and play therapy with children is commonly practised. The author stresses the advantages of group therapy among mothers and children. Patients often enjoy this form of group intercourse and continue it after discharge from hospital. The groups should usually be of 7-10 persons, but some therapists lecture to large audiences. The book includes a schedule of lectures as well as the author's impressions of results, accurate statistics are difficult to obtain. This book is worth studying by all concerned with the treatment of mental illness, especially institutions.

R. G. GORDON

OPHTHALMOLOGY

Principles of the Contact Lens By H. Treisman F.R.C.S., D.O.M.S., and E. A. Place (Pp 88, 40 illustrations 10s 6d) London Henry Kimpton 1946

L'Ophtalmologie Du Praticien By A. Cantonnet (Pp 172 85 figures 100 francs) Paris Librairie Maloine

Principles of the Contact Lens is the first monograph on this topic with which an ophthalmic surgeon has been associated, and the account is therefore more strictly clinical than those that have come from opticians. The authors devote about a third of their short study to the historical and optical aspects of the contact lens and then discuss the value of contact lenses in neuroparalytic keratitis, trichiasis, macular lesions, ptoxis, symblepharon, and pemphigus of the conjunctiva in addition to the more widely recognized uses. They describe two types of contact lens—the ground glass lens and the moulded glass lens—and mention plastic contact lenses towards the end of the book. The clinician should find particularly helpful the chapters dealing with the preliminary test, buffered solutions and tolerance.

The second book is one of the "Petits Précis" series, edited by Dr. Cantonnet. It is a remarkably complete summary of elementary ophthalmology and contains some matter not generally found in similar volumes, such as a fairly full account of binocular vision, the Cantonnet-Nouet alphabet for the blind, and a section on ocular hygiene. The author discusses treatment rather dogmatically and sometimes differs from the practice in Britain.

ARNOLD SORSBY

NATIONAL HEALTH SERVICE

Your Guide to the National Health Service A Manual for Patients, Doctors, Civil Servants, Hospital Officers and other Health Workers By A. David Le Vay M.S. F.R.C.S. (Pp 78 3s 6d) London Hamish Hamilton Medical Books 1946

Though this book is said to be for doctors as well as for others interested it is doubtful if the former will find it very helpful for, as the author indicates, the Act is merely a skeleton awaiting the flesh of Regulations, and most doctors who have studied it have found a good deal wrong with the skeleton. However though the author is a convinced believer in the Act and its consequences his book is worth reading much of it is factual and the style is clear and pleasant. Mr. Le Vay is aware that opinions may differ and his criticism is fair.

We may take exception to a few points for example, why has the author paraded once more that platitudinous buying and selling of practices, which he says is equivalent to the buying and selling of patients? No one who has bought a practice in an area served by several doctors could make such an assertion except under the influence of political propaganda. It is stated emphatically that the doctor will not be the servant of the State. Is this not playing with words? There is nothing derogatory about working in such a service, though most doctors would prefer to be employed

and paid by their patients, but when doctors have sold their practices to the State when their incomes come mainly, or even wholly, directly or indirectly from the State and when they can be excluded from the Service on the final decision of a Minister, it is not easy to understand in what sense they will retain their independence.

Certification is mentioned only briefly, but the author might have referred to the implications which many doctors see and fear in the future ubiquity and importance of medical certificates in connexion with the money benefits of National Insurance. Discussing expulsion from the Service and right of appeal to the courts the author very fairly marshals the arguments on both sides but agrees that the Minister should have the last word. He sees no reason why the taking over of the hospitals should lessen local voluntary work and interest and says, not perhaps with much conviction, there is plenty of room in hospital life for voluntary help—the linen rooms and the domestic side generally will remain open as before. He considers that 'central ownership of hospitals is only the predecessor to decentralization and the encouragement of local independence', and he concludes that 'the Service will be very good or very bad, and whether it is good or bad depends on whether there will be a tightening of bureaucratic control and on the wholehearted co-operation of the doctors. Yet how can anyone, with the embrace of post-war bureaucracy about him, hope for a slackening of its hold, fortified as it is in this case by the great powers given to the Minister and his staff. However, the optimist may be right. The book is honestly written, persuasive in tone, and not deliberately provocative.

ALFRED COX

TEXTBOOK OF ALLERGY

Allergy. By Erich Urbach, M.D. and Philip M. Gottlieb, M.D. Second edition, revised and enlarged. (Pp. 965. 410 figures. 70s.) London: William Heinemann (Medical Books) 1946.

In the second edition the authors have revised and enlarged this book and added new sections on the psychosomatic aspects of allergy, the Rh factor, allergic bronchitis, allergic cough and eosinophilic erythroderma. Of the 3,325 references almost 1,300 are new to this edition. The classification of the phenomena of hypersensitiveness—always a difficult problem—is rather involved. The authors' views on propeptan therapy, a form of treatment originated by the senior author, are far from being generally accepted by specialists in this field, and the dosage of pollen extract recommended in hay fever is considerably lower than that usually prescribed in this country.

This excellent reference book, up to date and well constructed, is probably the most complete on allergy yet published. It will be welcomed by those especially concerned with the subject and many chapters will interest all students of medicine though the general physician may find it heavy going in parts.

D. A. WILLIAMS

INCOME TAX

At Home with Income Tax. By R. W. Harris. (Pp. 178. 6s. 6d.) London: Stone and Cox 1946.

The aim of this book is to provide the ordinary taxpayer, in a compact and readily accessible form, with a guide to the income tax while avoiding complicated problems that are not of general interest. The author has succeeded to an extent quite unusual in this field. The general arrangement is excellent, the print clear, and the exposition simple (so far as simplicity is attainable in this subject) and illuminated by examples. The 'Notes for Professional Men' and those dealing with expenses are as useful as a broad description permits, the importance of taking income tax into account in connexion with the terms on which a share in a practice changes hands will particularly interest medical practitioners. The author discusses PAYE briefly, and mainly from the weekly wage earner's standpoint.

One of the hazards besetting this sort of book is that changes in the law are liable to make it out of date in a comparatively short time, but the fundamental features of the income tax, which are well explained here, are not likely to alter much. We can recommend it as the best available guide for 'the ordinary man and woman' for whom it is intended.

BOOKS RECEIVED

[Review it not include by notice here of the books received]

A Contribution to the Knowledge of the Influence of Canadian Tropical and Sex Hormones on the Growth of Rats. By J. H. Garverick and S. F. D. Joseph. (Pp. 116. 10s. 6d.) New York and Amsterdam: Elsevier Publishing Co. 1946.

A review of experiments on the influence of sex hormones on the growth of rats, showing the existence of a sex-dependent growth curve.

Handbook of Elementary Anatomy. By John J. Teasdale. (Pp. 165. 6d.) London: H. K. Lewis 1946.

A book of selected plates depicting the anatomy of the human body for students of medicine and biology.

The Birth of a Child. By G. A. D. P. (Pp. 99. 6s.) London: H. K. Lewis 1946.

The author explains the process of childbirth and the role of the midwife and general practitioner.

A Study on Oxygen Toxicity at Atmospheric Pressure. By W. T. L. O'Brien. (Pp. 93. 5s. 6d.) London: H. K. Lewis 1946.

A study on oxygen toxicity at atmospheric pressure, showing the effects of oxygen on the human body and the role of the general practitioner.

Postgraduate Obstetrics. By W. J. M. (Pp. 253. 10s. 6d.) London: H. K. Lewis 1946.

An American textbook of obstetrics, showing the latest developments in the subject and the role of the general practitioner.

Parenteral Alimentation in Surgery. By J. S. M. (Pp. 283. 21s.) London: H. K. Lewis 1946.

The author discusses the use of parenteral alimentation in surgery, showing the latest developments in the subject and the role of the general practitioner.

Anatomical Terms. By J. J. F. (Pp. 116. 10s. 6d.) London: H. K. Lewis 1946.

A pocket book to help students of anatomy, showing the latest developments in the subject and the role of the general practitioner.

The Care of Children from One to Five. By J. S. M. (Pp. 193. 10s. 6d.) London: J. and A. Churchill 1947.

The third edition of this well-known book, showing the latest developments in the subject and the role of the general practitioner.

The Treatment of Diabetes Mellitus. By J. S. M. (Pp. 116. 10s. 6d.) London: H. K. Lewis 1946.

A textbook on diabetes mellitus, showing the latest developments in the subject and the role of the general practitioner.

BRITISH MEDICAL JOURNAL

SATURDAY MAY 24 1947

THE EPIDEMIOLOGY OF TUBERCULOSIS

Prof J W S Blacklock, whose London University Lecture on the epidemiology of tuberculosis is printed in the opening pages of this issue of the *Journal*, has made two notable contributions to the study of this disease. The first of these, the report¹ on which is now a classic in the literature of its subject, was a combined morbid anatomical and bacteriological study of tuberculosis in children as seen post mortem during a seven-year period at the Royal Hospital for Sick Children, Glasgow. The former method of study made it possible to identify the site of the primary focus, the latter, since it included ascertainment of the type of tubercle bacillus, identified the source of the infection. The primary focus was abdominal in 101 cases, among tubercle bacilli isolated from such lesions, 54 strains were of bovine type and only 12 human. On the other hand, in 173 cases with a primary focus in the lung all but 3 strains (97.3%) of the bacilli isolated were of the human type. These observations, so unmistakable in their significance, did more than any others finally to refute the doctrine of von Behring and Calmette that the route of infection in infancy is almost exclusively alimentary, and that subsequent lung disease is due to migration of the bacilli from a glandular focus draining the alimentary tract. The extreme danger to young children of lung infection by direct inhalation was plainly revealed, indeed, in all but 5 of these 173 cases in which a primary thoracic lesion was found this infection was the cause of death. It appears that in Scotland this form of tuberculosis may have a higher mortality than elsewhere, but it is now more widely recognized as a highly fatal condition, particularly in the youngest age group. At the same time we have learned to look for the source of infection in pulmonary tuberculosis at all ages not in some reactivated glandular focus but in another case among the patient's recent household or other contacts.

This aspect of epidemiology is not forgotten in the lecture we print to-day. It is in fact amplified by a statement of the frequency with which different relatives in the household were found to be the source of an infection terminating in meningitis. But the greater part of the lecture deals with a fresh investigation pursued during the war on a considerably wider scale with the main object of determining the present relative frequency of infections due to the human and bovine types of tubercle bacillus. In this connexion, again, it is interesting to recollect that medical

science was misled for years by false belief emanating from the most authoritative source. Koch himself denied the pathogenicity of the bovine type of tubercle bacillus for man, and this was fully recognized only after the publication of the Final Report of the British Royal Commission in 1911. It was not indeed until 1929 that the late W T Munro demonstrated the existence of human phthisis due to the bovine type of bacillus. Our present detailed knowledge of the frequency of infection from cattle derives mainly from the work of the late Stanley Griffith, and, since the majority of his type determinations of bacilli from different human lesions were made fifteen or more years ago, they do not necessarily reflect the conditions existing to-day. It is important to know how much tuberculosis is being produced by the consumption of infected milk, age and geographical distribution, and the forms which it assumes. Such information is here made fully available for Scotland during the years 1943-4. The results acquire their chief interest when analysed geographically. It is shown, more clearly perhaps than ever before, that human infection with the bovine type of tubercle bacillus is a disease of rural areas where milk is consumed raw, and uncommon in cities where almost all milk is heat-treated if not pasteurized under licence. Thus the percentage of bovine infections in cervical adenitis was 46.2 in the towns and 77.8 in the country, the corresponding figures for cerebral tuberculosis were 20 and 42, and for surgical 20.1 and 45.4. It is even possible to relate the frequency of infections of bovine origin in various rural areas to the known condition of their cattle. In the Western area, including Ayrshire, where a large proportion of the herds are attested, bovine bacilli are much less often the cause of human disease than in parts of Scotland with a less enviable dairy-farming record.

An interesting corollary to this study is the work of J Sigurdsson,² pursued during the same period but under the shadow of German occupation in Denmark. This work involved, among other things, detailed inquiries and clinical investigations among families living in widely scattered and isolated farms. The author modestly remarks that his only means of transport for these extensive rural travels was a "bike". Denmark has made considerable progress towards the eradication of tuberculosis in cattle, a policy of permissive and compensated slaughter has been pursued since 1932, and many areas are free from the disease. On the other hand, others remain where it is still common, and owing to the thorough system of veterinary control the condition from this point of view of every area, and indeed apparently of every farm, is known. Sigurdsson's principal material consists of 566 type determined cases of pulmonary tuberculosis or pleurisy, of which 165 came from rural areas. No fewer than 67 of these 165 (40.6%) were infected with the bovine type of tubercle bacillus—quite the highest proportion ever observed—whereas in only 3.6% of the 362 purely urban patients was this type of infection found. The novel feature of this investigation follows: it consisted of pursuing inquiries into the records of the cattle with which the rural cases had been in contact. The result was to show that no less than 94% of the patients who had

¹ *Tuberculous Disease in Children*. Med Res Cncl Sp Rep Ser No 172 1932. London.

² *Acta tuberc scand*, 1945 Suppl XV.

an infection of bovine type had been in contact with "strongly tuberculous" cattle within the past two years. Sigurdsson is convinced that the inhalation of bacilli in stables containing animals with pulmonary disease is the main cause of these infections. Support for this contention is afforded by the sex frequency, males being more affected and more occupied than women in stable work, and by the demonstration of living tubercle bacilli in the dust and dirt of such stables. His further observations consisted of examining all members of the households of 200 farms in the parish of Grimstrup, at one half of which all the cattle were negative tuberculin reactors, whereas in the remainder they were "strongly tuberculous". Whether judged by the tuberculin reaction or by clinical or radiographic evidence of disease, households in the second category showed the higher percentage of infection. In many of these cases the route was doubtless alimentary. There are many other points of interest in this extensive study, which includes a comprehensive review of other—particularly Scandinavian—work. The author is convinced, for instance, that the prognosis is no better when human phthisis is due to the bovine instead of the human bacillus. He shows that the bovine type may spread from man to man, and from man to cattle, as well as from cattle to man. But the chief importance of his work is in showing the danger to human beings not only of consuming infected milk but of contact with infected animals in the stable. Evidence of direct infection from cow to man was also provided in this *Journal* three years ago by L. J. Cutbill and A. Lynn, of the Cheshire Joint Sanatorium. That infection by inhalation may occur in these circumstances has certainly not been generally recognized, and the risk is one with which farming people should be made familiar.

OXYGEN POISONING

As men descended to ever greater depths under water a number of symptoms were observed whose causes were gradually disentangled. The most important were those due to bubble formation on decompression. These can be prevented by a suitable time-table for ascent in stages. However, other symptoms are most marked while air at high pressure is being breathed. They are probably due to the fact that all gases are poisonous if breathed at sufficiently high pressure. Many solids and liquids are not poisonous, for the good reason that the blood does not dissolve them in toxic quantities. But the amount of gas taken up is proportional to its partial pressure. Behnke and his colleagues made the very remarkable discovery that not only nitrogen but argon is a mild narcotic at high pressures. What is even more surprising is that, per weight absorbed, nitrogen and argon are just about as narcotic as nitrous oxide. When breathing air at a depth of 300 feet—that is to say under 10 atmospheres pressure—a diver is exposed to a partial pressure of nearly eight atmospheres of nitrogen. Nitrous oxide is about forty times as soluble in blood as nitrogen, so the diver absorbs about the same volume of nitrogen per minute as he would of nitrous oxide

at atmospheric pressure from a mixture containing 20% of this gas. He does not lose consciousness but becomes rather stupid and irresponsible. Nitrous oxide and ether may be two or three times as narcotic as nitrogen per weight absorbed. They are certainly not five times as narcotic. They are more efficient as anaesthetics because they are more soluble both in water and in lipids, and for no other reason. Hydrogen and helium are not appreciably narcotic at ten atmospheres pressure. They may well be so at five or a hundred atmospheres.

Many gases have a marked physiological effect at pressures considerably below that at which they could be expected to have any narcotic action. One of these is oxygen. The experiments which K. W. Donald described in the last and the present issue of the *Journal* were part of the preparation for attacks on enemy ships such as the *Tupiza*, carried out by small groups of divers. Oxygen has a double advantage for such work. Not only does a diver carry far less oxygen than air for a given stay under water, but he need not betray his presence by bubbling. If air is used all the nitrogen in it must be discharged as visible bubbles. But a well-trained man can use up almost all the oxygen if this gas is supplied in a pure state. It had been known since Paul Bert's work of 1878 that oxygen is convulsant when breathed at high pressures. But up to 1942 there were no quantitative data as to its effect on men. Dr. Donald describes the work carried out at the Admiralty Experimental Diving Unit in 1942 to 1943. Not only were large numbers of men subjected to high pressure oxygen both in compressed air and under water, but repeated experiments were done on the same individuals. As it is perhaps unlikely that the work will ever be repeated on so large a scale it is to be hoped that the results will be published in full so that a complete statistical analysis is possible. From a practical point of view the most important conclusions reached were the extreme variability of tolerance, both between different individuals and in the same man from day to day, and the fact that tolerance under water was less than in compressed air. Convulsions have occurred at a depth of only 40 feet. Thus J. S. Haldane's misconception which led him to recommend that oxygen should not be used at pressures exceeding two atmospheres absolute, or 33 feet of sea water, would seem to have been justified by practical experience. Under war conditions it can be used and has been breathed at great depths. A one per cent chance of convulsions is a small additional risk to a man who intends to fix a mine under an enemy battleship. But it is not a risk which should be taken in peacetime.

Apart from the work described by Donald, numbers of experiments were done on civilian personnel. When the results are published, while Donald's main conclusions are not likely to be shaken, some of them may be seen in a slightly different perspective. In particular the effect of oxygen on the respiratory tract will perhaps appear to be a limiting factor in certain types of dive, though it was not so in those investigated by him. In spite of the careful biochemical work of Dickens, the cause of oxygen convulsions is completely obscure. The first requisite for its elucidation will be the measurement of the partial

pressure of oxygen in the venous blood leaving the brain just before a convulsion. Recent technical advances render such a measurement entirely possible even in human subjects, let alone animals. If the partial pressure of oxygen in the brain just before a convulsion is found to be several atmospheres, then it is possible that the inactivation of enzymes which Dickens reports may be a causative factor. If, on the other hand, the partial pressure does not always rise above half an atmosphere some other cause will have to be sought. In any case research on this problem will clear up the question of how far the brain can protect itself from oxygen poisoning by vaso constriction, and thus throw further light on the fundamental problem of the control of cerebral circulation. Whatever the biochemical process behind oxygen convulsions it is likely to be simpler than that behind convulsions caused, say, by metrazol or picrotoxin, and, above all, it is more likely to throw light on the causation of epilepsy. The research in question shows, clearly both the good and the bad points of much research done in connexion with the war. On the one hand quantitative data were obtained on men on a scale which has so far been quite impossible in peacetime. On the other hand, on account of the urgency of the practical problems in view, it was impossible to investigate the physiological processes at work in full detail. As a field for further research oxygen poisoning remains wide open, but unfortunately the technical equipment needed is rather expensive.

Similar problems could and should be tackled in peacetime. For example, the vapours of various solvents cause a good deal of ill-health and occasional deaths. But we do not know whether it would be possible to lower the risk by eliminating specially susceptible workers, as is the case with oxygen poisoning. Again, the inhalation of textile dusts is a steady source of death from nephritis and a group of conditions whose common factor is hyperpiesia. We know nothing of the biochemical processes at work, which should clearly be studied in animals before any experiments are done on men. Industry is as important as war, being indeed a prerequisite for modern war. If work on a similar scale to that of the Admiralty Experimental Diving Unit is done in the industrial field in the next generation, British industry may become a model of hygiene to the world in the twentieth century, as it was a model of productive efficiency in the nineteenth.

PLASMA MEPACRINE RECONSIDERED

The control of chemotherapeutic remedies by estimations of their concentration in the blood first came into general use in the case of the sulphonamides, following the work of Marshall and his colleagues. The methods applied were simple and the procedure became popular, especially in the United States where at one stage of the war it was reported that all the scientific medical men were "blood-level-minded". Accordingly, in 1942, when mepacrine (atebrin, quinacrine) began to be used to control malaria, it was natural that one of the first steps should be the study of its concentration in the different body fluids. Appropriate methods for this purpose were devised by Brodie and Udenfriend and by Masen, based on the extraction of the mepacrine by ethylene dichloride with suitable adjustments of the pH and measurement of the fluorescence of the

material obtained. The question was studied by Shannon¹ and by many other American and British workers.

Sulphonamides are distributed approximately equally through most of the body fluids and tissues. Mepacrine behaves quite differently, since it has a high affinity for protein and for certain types of cells. Most of the mepacrine is stored in the tissues and only a small proportion is found in the blood. The concentration in the skin is approximately 80 times that of the blood, in the muscle 50 times, and in the liver 2,000 times. In the blood itself distribution is uneven. The concentration in the erythrocytes is up to twice that of the plasma, and in the leucocytes over 200 times. The concentration in whole blood is approximately four times as great as that in the plasma. Finally, of the mepacrine in the plasma 80-90% is bound to plasma proteins and 10-20% is dissolved in plasma water, presumably it is this last fraction which is in equilibrium with the mepacrine in the tissues. In view of this complex distribution there was much discussion during the war as to which concentration of mepacrine—in plasma, in blood, or in some other fluid—was the most important. On the authority of Shannon and his colleagues it was generally agreed that plasma mepacrine was the most reliable indication of the level of mepacrine in the other tissues of the body. A great deal of work was done on this assumption—for example, the extensive observations made on volunteers at Fort Knox,² and all aspects of the dosage of mepacrine and of its suppressive and therapeutic actions against malaria were related to plasma mepacrine levels.

The whole basis of this work has now been questioned in a recent paper by Marshall and Dearborn, working in the laboratory which launched "blood concentrations" into modern therapeutics. They studied the therapeutic action of mepacrine in the malaria produced in ducks by *Plasmodium lophurae*, the host-parasite combination which has been most widely used in recent American laboratory work on malaria. Ducks maintained on a constant daily dosage of mepacrine showed marked variations in the plasma concentration of mepacrine, both between different ducks and in the same duck on different days. These variations are due mainly to variations in the distribution ratio between plasma and tissues, most of the compound being stored in the latter. (Although not mentioned by Marshall, much of this variation might well be due to changes in the level of ammonium ions, since even low concentrations greatly influence the distribution of mepacrine between cells and body fluids.^{3 4}) The concentrations of mepacrine in the tissues and in the erythrocytes were much less variable than those of the plasma. There was little or no correlation between plasma concentration and therapeutic effect, but there was good correlation between dosage and therapeutic effect. Although this work has still to be confirmed, and it remains to be shown that what happens in ducks also happens in man, this paper calls for reconsideration of the basic assumptions of investigations on mepacrine. It does not invalidate all studies of the concentrations of drugs in body fluids, it merely points out that in the case of mepacrine the plasma concentration is not such a reliable indicator as was previously believed. In that case there might be much to be said for going back to the estimation of its concentration in whole blood, taking precautions to check the leucocyte count. The whole blood concentration is much easier to measure than the concentration in the plasma, it can be done by a simple portable, and cheap instrument described by King and Gilchrist.⁵ However, mepacrine is rapidly becoming out of date. From

1942-5 it was of enormous military importance in controlling malaria in the Pacific and Mediterranean areas. It will now be replaced gradually by paludrine, chloroquine, or other new antimalarials yet to be discovered. So perhaps this challenge to accepted beliefs will not necessitate as much revision of previous work as would otherwise have been the case.

A minor point of some interest is illuminated by Marshall and Dearborn's paper—namely, to what extent the substance present in the blood or tissues is unchanged mepacrine and to what extent it is merely an inactive degradation product. Taggart has studied material from Marshall's ducks. He reports that of the fluorescent material obtained from the liver one day after a single dose, 90% is unchanged mepacrine, but 14 days after a single dose only 15% of the fluorescent material is really mepacrine and 85% consists of degradation products, which are presumably inactive. Once again it has been shown that the application of analytical chemistry to therapeutics is beset with pitfalls and that a broad and balanced judgment is needed properly to assess the valuable contributions that can be made to clinical practice by these measurements.

VACCINIA AND ECTROMELIA

In 1941 Hirst¹ and McClelland and Hare² described the agglutination of chicken red-blood cells by material containing influenza viruses A and B. Since that time Burnet and his co-workers³⁻⁵ have applied this new technique to the study of a large number of viruses, and similar types of reaction have been given by viruses previously considered to be unrelated. Specific agglutination of the red blood corpuscles of many other species has also been useful in differentiating certain of the viruses. The Melbourne workers⁶⁻¹⁰ have recently described a possible relation between the viruses of vaccinia and infectious ectromelia of mice which gives rise to much interesting speculation. Red blood cells from only 50% of fowls are fully susceptible to agglutination by these viruses. With the exception of mouse red-blood cells, which are agglutinated specifically by ectromelia virus only, both viruses gave negative results with three ducks, one man, two calves, three rabbits, and two rats. Two of five pigeons gave susceptible cells. Thus the susceptibility of mouse cells to ectromelia virus was not paralleled by any power of vaccinia virus to agglutinate cells from the species most susceptible to its pathogenic activity. The haemagglutination with both viruses is of the same character, but the haemagglutinins of these viruses differ from the influenza viruses in several respects. The agglutination is best shown at 37° C, in contrast to the influenza viruses, which give more satisfactory readings at lower temperatures. The haemagglutinin of ectromelia is distinct from the virus particles, whereas influenza virus haemagglutinin is a function of the actual virus particle. Ectromelia virus haemagglutinin is susceptible to inhibition by specific immune serum and to almost equal titre by vaccinia immune serum. None of the normal human, rabbit, or calf sera at a dilution of 1:10 showed any inhibition of agglutination. This contrasts with the usual finding with influenza virus strains.

There was in addition active cross immunity between ectromelia and vaccinia viruses in rabbits and mice. The two viruses have a number of other common features. Both are relatively robust forms which survive well in broth filtrates or glycerolized emulsions at ordinary refrigerator temperatures. The elementary particles of both are probably about the same size. In the chorio-allantoic membrane of the developing chick embryo the difference in lesions is striking, but Burnet considers they can be ascribed to differences in the vigour of multiplication of the two viruses in embryonic cells. It is unfortunate that little or no evidence is available as to the natural occurrence of ectromelia in wild mice or other rodents. Burnet concludes that in general there seem to be no physiological and biological differences between vaccinia and ectromelia viruses great enough to preclude the possibility of a common origin. The differences between the viruses are, however, extensive enough to make it certain that if they have a common origin the two lines have undergone a long evolution in dissimilar hosts. Further comparative study of the other mammalian pox viruses using the red cell agglutination technique may help to elucidate the evolutionary history of the group.

ACUTE NON-SPECIFIC GASTRO-ENTERITIS

Acute gastro-enteritis affects persons of all ages but is rarely fatal except in the very young and the old. Some of the causes of this disease are known such as the Salmonella and dysentery groups of organisms, food poisoning due to bacterial exotoxins, and also food poisoning caused by the toxic products of bacterial growth. There remains a large proportion of cases in which no specific cause can be found and in which the clinical syndrome varies thus suggesting that there is more than one infective agent responsible. Included in this group is true neonatal diarrhoea of the type reported some months ago at Derby,¹ where no adults were affected but there was a high mortality among the babies. Maternity hospitals in Oxford and Leicester had another type of outbreak in which the nursing staff, mothers, and babies were affected, though on the whole the disease was less severe than at Derby. There were no signs of upper respiratory tract infection in these outbreaks, and the same applies to the two epidemics in Cornwall described by Hargreaves elsewhere in this issue (p. 720). In other outbreaks, particularly those affecting adults, there have been signs of faecal infection: this was true of the epidemics discussed by Bradley² and by Reimann.³ There have also been large numbers of cases among the general public in widely separated parts of the country. Here the disease has had a very sudden onset, the first symptom being vomiting followed by diarrhoea, with a fairly rapid recovery, the illness lasting about three days.

It has been suggested that a virus is responsible for acute gastro-enteritis, a view supported by Reimann and discussed by Hargreaves. Work in this country on lines similar to Reimann's has consistently given negative results but it is possible that the infective agent in the cases studied was different, as they did not show faecal involvement. Acute non-specific gastro-enteritis is often diagnosed as "gastro-influenza," but it is unlikely that the accepted influenza viruses A and B play any part, so far as incidence is concerned the two diseases do not bear any relationship to one another. Gile⁴ has drawn attention to certain strains

of *Str faecalis* which are active producers of tyramine, a substance possibly toxic to young babies, such strains have been isolated from a few outbreaks of infantile diarrhoea. Tyramine would be non-toxic to adults, however, because they are able to break it down.

There is increasing interest in the part played by the coliform group of organisms and their possible pathogenicity. Work by Kauffman⁵ and by Vahlne⁶ has laid down a classification of this group based on serological methods. Vahlne found a high incidence of two or three groups among coliform strains isolated from cases of cystitis, appendicitis, and cholecystitis, so certain coliform strains may perhaps be accepted as being more potentially pathogenic than others. Stuart⁷ and Christensen⁸ have suggested that these organisms are responsible for gastro-enteritis in adults but the evidence they give is not conclusive.

Though the aetiology of acute non-specific gastro-enteritis is unknown there are circumstances which favour its occurrence. The majority of cases of neonatal and infantile diarrhoea appear to arise in institutions, a fact to be accepted with reserve since there are no reliable figures on which to assess the incidence in the general population. Nevertheless, descriptions of recent outbreaks refer to overcrowding in maternity units and nursery schools and stress the inadequate nursing facilities. It is obvious that these conditions are ideal for the spread of any infective agent.

Kershaw, in another part of this issue (p. 717), ascribes some forms of acute gastro-enteritis to local chilling of the abdomen. This may be a factor in the cases which he describes, but it is unlikely to operate in Britain. Here chilling predisposes the patient to the most common of all infections in this country—that of the upper respiratory tract. The moral of Kershaw's article lies in its insistence on adverse hygienic and other conditions as being important factors in determining the appearance of a large number of cases of gastro-enteritis in a community in which the disease is sporadic. Though interest may be centred on the actual agent responsible for disease, it must be remembered that any condition which lowers the resistance of the individual will favour the onset of infectious disease, and where the agent is only potentially pathogenic, then external circumstances may in fact determine the onset of an epidemic in a community.

SWISS RATIONS

Prof. A. B. Fleisch was president of the Swiss Commission *federale pour l'alimentation de guerre*. His account⁹ of food control is particularly interesting because the Swiss problems were very similar to ours. The Swiss had imported over half their food. In order to check the growth of a black market they aimed at supplying enough calories, and tried therefore to produce the maximum energy value from their soil. Prof. Fleisch discusses the calories and protein for human consumption obtained per acre from various crops and from livestock. The cultivated area was doubled, and potato crops rose to two and a half times their pre-war level. Livestock, not excluding milch cows, was reduced, though the numbers of pigs and hens were not cut down as drastically as in Britain. The extraction rate of flour was raised to 94% or over for a short period and was kept at about 90% for most of the

war, so long as the rate was not over 90% the flour proved satisfactory.

The Swiss were not able to import butter or substitutes, their 2-oz. ration was made from milk produced at home. They were left with the problem of the best use of skim milk, previously used for feeding livestock, and few people chose the 2 pints which could be taken in place of 1 pint of whole milk. There was also little demand for dried skim milk. In spite of propaganda to stimulate the use of skim milk for human consumption 38% was still used for feeding livestock. Rationing was introduced gradually from November, 1939, onwards. The supply of milk was restricted from January, 1942, inequality of distribution caused much bitterness. Milk was rationed from October–November, 1942, at the same time as bread, which had been much used for feeding hens and other livestock. Extra rations were allowed for adolescents aged 12 to 19, for pregnant women, and for three categories of workers in amounts graduated according to the heaviness of their work. Children up to 6 years received special rations. A low-price ration card was introduced which allowed the purchase of more of the cheaper and less of the dearer foodstuffs without alteration of calories, protein, or fat. Canteen meals were considered as a means of saving fuel, but were held to be impracticable, since Swiss workers have a two-hour break in the middle of the day. After the rationing of bread and milk had begun, coupons had to be given up for school meals. In the winter of 1944–5 the children could no longer afford these coupons, and the number of meals supplied fell, during the summer of 1945 coupons were no longer demanded.

The number of calories taken by a normal consumer, with average consumption of unrationed foodstuffs, was in the neighbourhood of 2,100 per day, except during the middle half of 1945, when the lowest level reached was 1,783 calories in May. Prof. Fleisch compares this intake with the average calories taken per head according to *Food Consumption Levels in the U.S.A., Canada, and the United Kingdom*. This comparison is most misleading. This pamphlet, as is expressly stated, gives the calories per head calculated from the amount imported and produced and not, as has been incorrectly stated in a White Paper, "at the retail level." The comparable figure for the number of calories taken in Britain per head was not between 2,900 and 3,000 but about 2,300.

The death rate from tuberculosis remained about the 1938 level, but the number of notifications in 1945 was more than twice the total for 1939. Death rates from other diseases decreased. There was less sickness among school children, and their average heights and weights were maintained. The Tuxford index fell during the period of extra scarcity in 1945 and then recovered. There was also much less dental caries. The Swiss Paediatric Association discussed rickets in June, 1943, and did not consider that it had become more frequent or severe. Opinion leaned towards the use of single large doses of vitamin D in prophylaxis of the children in Zurich, 60% were so treated in the winter of 1942–3.

From the autumn of 1941 to the spring of 1946 the weights and haemoglobin levels of 700 persons were recorded. Both fell slightly in 1945 and then rose again. Apart from this there were seasonal variations, weights being highest in the winter and haemoglobin values in the summer. There was much agitation in the newspapers and in Parliament for vitamin supplements, but the great majority of doctors did not consider that adults needed them. In a short experiment at Zurich supplements of vitamins B₁ and C were given to school-children. They had no detectable effect on growth but were thought to improve appetite and to reduce fatigue.

LEPROSY IN BRITAIN

Since the war a small number of cases of leprosy have been detected in Britain among returning soldiers and prisoners of war from the Far East. We are indebted to the medical secretary of the British Empire Leprosy Relief Association for the following brief notes of six cases already seen.

Case 1—Male, aged 38, civilian internee, Far East. Diffuse, slightly raised irregular, reddish brown inflamed areas on face, trunk, arms, and legs. History of slow spread for the last two years. No lesions on genitalia lower abdomen, or any flexor surface. Scrapings from the corium of the affected skin showed abundant acid fast bacilli. Diagnostic points: Far East history, under bad conditions, long duration of lesions, distribution, acid-fast bacilli.

Case 2—Male aged 34, Far East prisoner of war. Lesions on upper and outer left arm and right loin of eight months' duration—about 2 in (5 cm) in diameter, roughly resembling ringworm. Edge slightly raised and dull red with well defined margin. Area of skin enclosed by the ring is flattened and slightly hypopigmented. Definite anaesthesia to light touch. No acid-fast bacilli found.

Case 3—Female, aged 49, civilian internee, Far East. Lesion just above and on outer side of left knee. Duration three years. Lesion oval shaped roughly resembling ringworm, long diameter about 2½ in (6 cm), margin pale yellowish red and slightly raised. Both centre and margin of lesion show definite anaesthesia to light touch. No acid fast bacilli found.

Case 4—Soldier with service in Far East. Lesion on left loin for last eighteen months—about 4 in (10 cm) in long diameter oval plaque slightly raised and about the colour of a subsiding erysipelas. Anaesthesia to light touch. No bacilli.

Case 5—R.A.F. officer with service in several theatres. Lesion of two years duration. Faint diffuse blush on upper right shoulder with no defined edge. No anaesthesia. Scraping from corium showed acid fast bacilli.

Case 6—Soldier with service Far East. Diffuse yellowish brown infiltration of face and irregular ill defined patches over body. Both ulnar nerves thickened above elbow and tender on palpation. Duration four years. Scrapings from the corium show masses of acid fast bacilli.

Cases 2 and 3 are both early tuberculoid leprosy, the diagnosis being made from the clinical appearance and the anaesthesia. Bacilli were not found. Case 6 is a case of advanced leprosy, infective to children on prolonged contact, which unfortunately went on for four years before being diagnosed. Other cases undoubtedly exist and it may be expected that more will develop. The diagnosis of leprosy should be kept in mind in all cases of resistant skin lesions of long duration where there is a history of service and residence in countries in which leprosy is endemic. The importance of early diagnosis and treatment need not be emphasized.

LEPROSY IN THE EMPIRE

An exhibition arranged with the object of drawing public attention to the incidence of leprosy in the Empire is to be held at Overseas House, St James's, from June 11 to 21. The British Empire Leprosy Relief Association is responsible for the exhibition which will be opened by Lord Wavell, and will be named 'Who Walk Alone,' after the American best seller by Perry Burgess. At a preliminary Press conference Sir Bernard Bourdillon, chairman of the Association gave the number of lepers in the Empire to-day as two millions of whom 97.5% were in India and Africa. A great deal had been done by means of self supporting settlements, with well-planned houses and streets, each settler having his own farm land and some job to do within the settlement. The organization of settlements had greatly diminished the former concealment of the disease, which of course encouraged its spread and it was shown that with good attention and care the leper's expectation of life might be almost normal. Help in the treatment of leprosy had been afforded by the sulphonamide drugs, but these were expensive as compared with the usual chaulmoogra oil treatment. The seeds of the chaulmoogra tree were grown in the settlements themselves, so that each injection cost only about sixpence.

Dr G. A. Rynie, medical secretary of the Association and formerly of the Sungai Buleh Leper Colony, Malaya, said that he expected a temporary increase in the number of lepers in this country as a result of the return of the 14th Army and prisoners of war from Burma. Perhaps 30 cases might come to light during the next five years. There was little fear of further infection during this incubation period. The exhibition will illustrate the progress of the fight against leprosy, the magnitude of the problems yet to be solved, and the urgent need of funds to enable the activities of the British Empire Research Association to be more widely extended.

NATIONAL HEALTH SERVICE ACT

EXECUTIVE COUNCILS

The Minister of Health on May 15, laid before Parliament Regulations relating to the executive councils to be set up under the National Health Service Act 1946. This is another of the essential preliminary steps in the organization of the new Health Service. The Fifth Schedule appended to the Act states that an executive council shall consist of a chairman appointed by the Minister of Health and 24 other members: 8 appointed by the local health authority, 4 by the Minister, 7 by the local medical committee, 3 by the local dental committee, and 2 by the local pharmaceutical committee. The Act envisaged the setting up of executive councils in each county and county borough to organize locally the health practitioner services.

The new regulations came into force on May 15 and do not apply to the Isles of Scilly. The procedure to be adopted is as follows:

A local health authority, local medical committee, local pharmaceutical committee or local dental committee shall forthwith give notice in writing to the Minister of the names and addresses of any person appointed by them to be an original member of the council and to the clerk of the council of the name and address of any other member appointed by them. The clerk of the council shall forthwith inform the Minister of the names and addresses of any members so notified to him.

The first chairman of the council shall hold office until March 31, 1949. Of the original members of the council one-third shall retire on March 31, 1949, one-third on March 31, 1950 and the remainder on March 31, 1951. The order of retirement of the original members shall be determined by drawing lots at a meeting of the council held as soon as convenient after its constitution.

The term of office of members will be three years and members will be eligible for reappointment. Where a vacancy occurs by reason of the death, resignation or disqualification of any member, the vacancy will be filled either by a nominee of the Minister or by a person appointed by one of the electing bodies so as to maintain the balance of representation laid down in the Fifth Schedule.

Procedure

Questions considered by the council will be determined by the majority of the votes of the members present. Minutes will be kept by the clerk who is to be a person appointed by the council and approved by the Minister. The clerk and such other officers as may be necessary will be remunerated in accordance with scales approved by the Minister.

The council is to appoint a finance committee and other committees as necessary. Except in the case of the finance committee these committees may include persons who are not members of the council. The council may make rules and revoke standing orders for the regulation of the proceedings and business of the council and of its committees. The council is to meet not less often than once in every three months.

Supplementary Ophthalmic Services

It is laid down in Part III of these regulations that except in the case of areas exempted by orders made under subsection 4 of Section 41 of the Act, the executive council shall appoint an ophthalmic services committee. This committee will exercise

on behalf of the council the duty of making arrangements for the testing of sight and for the supply of optical appliances. The ophthalmic committee will have 8 members appointed by the executive council from among the members of the council other than those appointed by the local medical committee, and one medical practitioner nominated by the council from those members appointed by the local medical committee. Three other medical practitioners having the prescribed qualifications, 3 ophthalmic opticians and one dispensing optician will be appointed by such organizations as the Minister may recognize as composed of members of the professions concerned.

In this connexion and for the purposes of Part IV of the Act and the Seventh Schedule the expression "medical practitioners having the prescribed qualifications" means

A medical practitioner who has

(a) Completed an academic or postgraduate course in ophthalmology approved by the committee hereinafter in this paragraph mentioned and received a diploma or certificate in respect of such course, or

(b) Held for a period of two years an appointment as an ophthalmic surgeon or assistant ophthalmic surgeon on the staff of an eye hospital or a hospital having a special eye department, or

(c) Held any appointment for a period of two years affording special opportunities for acquiring the necessary skill and experience of the kind required for the services to be rendered, and who shall, to the satisfaction of the Minister acting on the advice of a committee to be recognized by him for the purpose of approving such qualifications, have had adequate, including recent, experience.

The original members of the ophthalmic services committee, which is to appoint its own chairman, are to retire on March 31, 1949. Thereafter the term of office of members shall be one year. Members will be eligible for reappointment. These regulations also define the "prescribed qualifications" for ophthalmic opticians and dispensing opticians.

PATENT MEDICINES

Proposals for Control

The Pharmaceutical Society of Great Britain has asked the Minister of Health to bring the sale and advertising of proprietary medicines under statutory control. The Society has submitted to the Minister a 14,000 word report, based upon five years' investigation. Since 1914, when the Select Committee of the House of Commons published its *Report on Patent Medicines*, newspapers, advertisers, pharmacists, and the manufacturers of proprietary medicines themselves have done much to suppress abuses, but the conclusion is reached that the position to day is little less objectionable than it was then.

"Throughout the pages of most newspapers and periodicals in general circulation, states the report, sufferers from all manner of diseases and ailments are offered beans, tablets, wines, powders, salts, pills, ointments, tonics, hormones, glands, and vaccines that will bring them youth, health, charm, slenderness, strong nerves, inner cleanliness, lively livers, freedom from pain, increased (or decreased) weight, iron for the blood, purer blood, vitamins, contentment, resolution, immunization, vitality and so on. The advertisers' claims are frequently so fantastic that one would not be surprised to find them offering secure jobs and large salaries into the bargain." To remedy this state of affairs the Society puts forward a number of proposals.

(a) The duty of securing the maintenance of proper standards for proprietary medicines and their advertisements should be placed by statute upon the Minister of Health in England and the Secretary of State in Scotland.

(b) In carrying out these duties, they should be assisted by an advisory committee including pharmacists, medical practitioners, and representatives of the appropriate Government departments, and persons with a specialized knowledge of the subject.

(c) A registrar having pharmaceutical qualifications will be needed, together with

(d) A register of medicines and manufacturers.

(e) The sale of unregistered medicines should be prohibited.

(f) Standards for medicines and for advertisements should be prescribed by regulations made on the advice of the Committee. These standards should include (i) a requirement that the disclosure of composition must be in approved words and quantities, (ii) the prohibition of false, misleading, or exaggerated claims, and (iii) the prohibition of offers of diagnosis through the post.

(g) Similar provisions should be applied to surgical appliances and to 'treatments'.

(h) Complaints of non compliance with the regulations would be heard by the Committee which would advise the Minister whether or not the medicine or the manufacturer should remain on the register, any action by the Minister would be subject to appeal to the High Court.

(i) The services of the inspectors of the Pharmaceutical Society should be available for the necessary duties of enforcement.

Probable Increased Demand

The introduction of a comprehensive Health Service is not expected in itself to minimize in any way the demand for patent medicines. The Select Committee prophesied in 1914 that the sales of secret remedies would tend to decrease because of the operation of the National Health Insurance Act. In point of fact the volume of proprietary medicine sales doubled during the next ten years. The public are not expected to react any differently to the new Health Service, nor is their right to self-medication denied. It is contended however, that protection is needed in the exercise of that right.

"Unless therefore," the report concludes, "appropriate steps are taken to provide this protection, the era of a comprehensive Health Service may bring with it the golden age for commercialized charlatanry, which makes a butt of the orthodox practitioners on whom the service depends and a victim of the public, to the prejudice of the Service. It is therefore desirable, before the compelling pressure of these selling methods can be exerted still further, to direct attention to the following conclusions which, it is suggested, are to be drawn from the facts set out in this report.

1 "Proprietary medicines are advertised in terms of the grossest exaggeration, advancing claims which are frequently fraudulent.

2 "The persistent and ubiquitous advertising of proprietary medicines makes the public conscious of disease, teaches that ill health is the normal condition of human beings, and encourages self-medication as a habit.

3 "The claims made for some medicines lead to the public's postponing seeking skilled advice and encourage symptomatic treatment, thereby prejudicing the success of treatment directed to the cause of the symptoms.

4 "Many advertisements for proprietary medicines are based upon creating an atmosphere of fear—fear of ill health or of an operation, of premature old age, of an incurable disease.

5 "Reliance is placed upon uncritical testimonials as evidence of the value of proprietary medicines.

6 "Exaggerated claims are made for medicines for the relief of chronic conditions, such as asthma and rheumatism, and hopes are held out which cannot be realized.

7 "By implication or indirectly the advertising of proprietary medicines undermines public confidence in a State Medical Service and in the registered medical practitioners at whose hands such a service must be provided.

8 "Questionnaires are sent to patients with the suggestion that the manufacturers of the medicine will diagnose from the patient's answer what his complaint is and what medicine should be given him. These forms are sometimes never looked at and there is evidence that the same medicine is supplied without regard to the information which the patient gives.

9 "Pamphlets and advertisements are published which advertise articles as sexual tonics.

10 "Excessive prices and fees are charged for some medicines and for some treatments and money that can ill be spared is extracted from the sick.

11 "Many advertisements are couched in scientific or semi-scientific terms, often meaningless or having a pretence to scientific advance, designed to impress or deceive uneducated and credulous people.

12 "Endeavours are made to circumvent legal requirements relating to disclosure of composition.

13 "Certificates of analytical bodies referring to qualitative and quantitative particulars are issued to proprietary medicine manufacturers on a commercial basis and are used by them in advertisement in implied support of claims concerning which the certificates have no relevance.

14 'Preparations are compounded in a manner and of such substances as to defy analysis and preclude the production of evidence at law as to composition'

15 "The advertising of proprietary medicines is so extensive that the influence of advertisers prevents the ventilation of reforms in the public Press and so derogates from the principle of the freedom of the Press"

16 The volume of advertising of proprietary medicines gives these articles a significance which is out of all proportion to their true value to the community'

According to the *Daily Telegraph* the Proprietary Association of Great Britain stated on May 16 "It is not easy in the absence of the report to comment in detail upon the findings of the Society. The censorship work of the Proprietary Association of Great Britain, the Newspaper Proprietors Association, the Newspaper Society, and other trade organizations has practically eliminated all undesirable forms of advertising."

PROPOSED LONDON CENTRAL HEALTH COMMITTEE

Under the National Health Service Act the London County Council becomes the local health authority for the county of London and has the duty of establishing a health committee. An administrative scheme has been submitted to the Council for dealing with the local and domiciliary health services for which the Council will be responsible after April 1, 1948. Some of these services are already administered by the Council others will be transferred from the city corporation and the borough councils while yet others are duties newly imposed by the Act. The scheme proposed represents a new departure in local government in London providing as it does for members of the city corporation and the borough councils to participate directly in the administration by the county council of the personal health services. The central health committee will consist of 46 members, of whom 30 will be members of the county council. One will represent the city corporation, and 9 the borough councils, the remaining 6 will be co-opted, after consultations with the regional hospital board and other appropriate bodies, in such a manner as to establish liaison with the hospitals and to secure the services of doctors and other experts. Of the 40 local authority members whose names are proposed 21 are women.

The terms of reference of this committee include the provision, equipment, and maintenance of health centres, the care of expectant and nursing mothers and young children, midwifery, the provision of health visitors, home nursing, vaccination and immunization, ambulance provision, and liaison with hospital and general practitioner services. This committee will also be responsible for all matters relating to the function of the LCC as local health authority under the Lunacy and Mental Treatment and Mental Deficiency Acts, and all matters it present the function of the county council concerning milk, food and drugs, registration of nursing homes and, at the request of the Education Committee, the medical treatment of school-children.

Medical Treatment of School children

The report presented to the Council proposes that the new Health Committee should be responsible for providing or making contractual arrangements for, the treatment (as distinct from the medical inspection) of school-children in accordance with section 48 (3) of the Education Act. This proposal, it states, will permit the progressive integration of the treatment side of the school medical services with those other services specially maternity and child welfare which it will fall to the Council to provide under the new National Health Service Act.

Debate has taken place as to whether the sanitary functions of the public health service including drainage and smoke abatement should be transferred to the Health Committee but it is felt they should remain where they are at present, combined with housing, and that the only concern of the new Health Committee at any rate for some years, should be health matters affecting the person.

Area Health Subcommittees

The Council had already decided that the administration of the local health services should be decentralized, and that so

far as practicable their day to day management should be entrusted to area committees. For this purpose it is proposed to split up the county of London into nine divisions each division comprising from two to five metropolitan boroughs. The City of London is included with Bethnal Green, Poplar and Stepney in one such division. Each of the divisions will have its health committee really a subcommittee of the large central committee and on each of these committees there will be members both of the county council and of the borough councils, the latter in about double the number of the former. Thus the largest of the divisions, comprising Hampstead Paddington St Marylebone St Pancras and Westminster, will have 23 local authority members 15 of them drawn from the borough councils. The smallest division is the one covering Hackney Shoreditch and Stoke Newington, with 8 borough council and 4 county council members. There will be on each committee up to six additional co-opted members. These divisional committees however are not likely to be set up until on or after the appointed day.

It is claimed for the scheme that it will bring into the administration of the personal health services in addition to the members of the county council, more than 100 members of the City corporation and the borough councils 10 of them on the central committee and 92 on the divisional committees. It will also bring in 60 members—6 on the central and 54 on the divisional committees—co-opted for their special knowledge and experience of health and hospital matters.

RAMC WAR MEMORIAL FUND

The Royal Army Medical Corps—which next year celebrates its jubilee as a united corps under that name and also its first appearance in the field in the Khartoum expedition of 1898—is making a public appeal for a fund to commemorate the achievements of the Corps during the war. At a Press reception held at the Royal Army Medical College, Millbank, Sir Alexander Hood, Director General A.M.S. described the aims in view. The fund is to be devoted to the welfare of families of all ranks of the Corps who fell in the war also of all ranks who served and whose families may be in need through sickness or other misfortune. The term 'welfare' includes monetary grants assistance in training for civil technical qualifications help with the education of children and other purposes. A relatively small amount is to be set aside to provide a permanent memorial incorporating the names of the fallen. Sir Alexander Hood explained that it was considered desirable that no large amount should be spent on an expensive memorial in wood or stone further any central memorial, such as the equipment of a hospital or the making of a memorial garden would necessarily be accessible only to a small section of those interested. It is not proposed to capitalize any large sum and use the interest only but to distribute the money in such amounts as to afford substantial help in individual cases, and it is expected that the fund may serve within six or ten years. After the last war a similar fund amounted to £20,000 and it is hoped to beat that record. The personnel of the Corps with the help of the Emergency Medical Service have already raised £9,000.

An appeal for such a body as the R.A.M.C. is necessarily more difficult than for a territorial regiment which can draw upon its county or city associations. Moreover as the work of the R.A.M.C. is not combantant but humanitarian and has brought succour to every branch of the Army, as well as to many sailors and airmen—during the recent war well over four million sick were treated by the Corps—it is considered justifiable to bring the fund to the attention of the wider public. Sir Alexander Hood is president of the fund and the list of vice-presidents includes several former D.G.A.M.S.s and other senior officers. Each of the Commands is represented on the committee which also includes N.C.O.s and men. The honorary treasurer is Mr C. G. Randolph, director of Messrs Glyn Mills and Co., of Kirkland House, Whitehall. The fund of which H.M. the Queen is patron has received special permission from Field-Marshal Lord Montgomery to include in the appeal his message to the Corps: "admiration and high regard to a Corps whose contribution to victory has been beyond all calculation."

Reports of Societies

PENICILLIN IN NEUROLOGY ANGLO FRENCH MEETING

A joint meeting of the Section of Neurology of the Royal Society of Medicine and the Société de Névrologie de Paris was held on April 15 in London, Dr DOUGLAS MCALPINE presiding.

Sir HUGH CAIRNS said that four years ago Sir Howard Florey presented his department at Oxford with some penicillin. The first preparations contained only 50 to 100 units per mg and were very impure compared with the crystalline preparation of penicillin II now available, which contained 1,650 units per mg, but the dosage of penicillin given intrathecally worked out then had survived the coming of more abundant supplies. In gunshot wounds of the brain it was no use placing penicillin in the brain wound and hoping that all infection would be quelled, all indriven matter and necrotic brain tissue must be removed. In the absence of blockage of the pathways penicillin given intrathecally spread to all parts. A single intrathecal injection of 12,000 units would usually maintain an adequate concentration in the cerebrospinal fluid for twenty-four hours providing levels of between 0.3 and 0.6 unit per ml. Occasionally the penicillin disappeared more rapidly, so that when it was essential to maintain the concentration of penicillin in the cerebrospinal fluid it was better to give intrathecal injections twelve-hourly. The importance of a moderate intrathecal dosage was emphasized, he had never exceeded 20,000 units in a single dose. In most cases the lumbar route sufficed, but if the cerebrospinal pathways were blocked this route became ineffective. The cisternal route might be difficult in a case of meningitis, and there should be no hesitation in using the ventricular route whenever a block was suspected.

Systemic Administration

Penicillin given systematically, Sir Hugh Cairns continued, did not pass into the cerebrospinal fluid in appreciable amounts. Patients had developed relapses and had had pneumococcal meningitis when on systemic penicillin. However, it helped to overcome the primary source of infection and to deal with septicaemia when that was present, either from the primary focus or from relapsing meningitis. Penicillin also passed freely from the blood stream into the subdural space (though this statement should be made with some reserve because so far its proof rested on only one case). The sulphonamides were particularly important at the stage when the intrathecal administration of penicillin was being stopped. The immediate treatment of bacteriologically unidentified meningitis should be by sulphonamides and systemic penicillin in full doses, arrangements should be made for continuing such treatment during the transit of the patient to hospital, though there would be fulminating cases where that recommendation would not hold. In brain abscess most of the causal bacteria were sensitive to penicillin. Cerebellar abscess had presented a difficult problem, but with the aid of penicillin—and, where there was a Gram-negative organism, of streptomycin—success had been obtained, though this in no way diminished the need for unremitting expert care in each individual case. For preventing the infection of operation wounds penicillin powder was used as a routine, there was evidence that it was effective in diminishing post operative infections.

In conclusion Sir Hugh Cairns said that penicillin was not miraculous in its effects. Given access to sensitive organisms it would assist in their destruction for so long as its concentration remained adequate. The use of penicillin demanded a greater degree of precision and systematic planning than had hitherto been accorded to less powerful remedies.

Penicillin in Meningitis

Dr HONOR SMITH said that in pneumococcal cases penicillin was given intrathecally once or twice daily for a minimum of five days in doses of 8,000 to 16,000 units made up in a solution with 2,000 units per ml. Larger doses, especially when given in concentrated solution were no more effective and might be harmful. Lumbar, cisternal, and ventricular routes had been used for injection, and occasionally, in difficult re-

lapsing cases, all three had been found necessary, but in uncomplicated cases the lumbar route was safe and effective. Of the sulphonamide supplements sulphadiazine was the drug of choice. The sulphonamides might be given as soon as meningitis was diagnosed to tide the patient over the interval which might elapse before treatment with intrathecal penicillin could be given. The complications most frequently seen were spinal block and relapse. Treatment of the relapse did not differ from that of the initial attack, and if the relapse was promptly recognized and energetically treated the prognosis was good. Fifty unselected cases of pneumococcal meningitis had been treated, with 39 recoveries. Of the remaining 11 patients, two died from causes other than the meningitis, and four were virtually moribund when admitted to hospital. In the treatment of meningococcal meningitis intrathecal penicillin was rarely required, excellent results being obtained by treatment with sulphonamides alone.

Penicillin in Neurosyphilis

Dr C. C. WORSTER DROUGHT said that immediate results in early syphilis had been shown to equal if not to exceed those obtained with intensive arsenical and bismuth therapy, and there was little or no risk of toxic reactions. In cases of early syphilis treated with penicillin alone a moderately high relapse rate soon became apparent. Much remained to be learned in working out the most satisfactory method of applying penicillin in these conditions. Intravenous penicillin had little to commend it. The continuous drip technique was clumsy and there was a risk of thrombophlebitis. Relapse seemed to be more frequent after intravenous than after intramuscular injection. Recently there had been a tendency in the United States towards larger doses, several authors advocating 40,000 units every three hours up to a total dosage of 4 million units. Others thought that equally good therapeutic results were obtained by giving much larger doses of penicillin at longer intervals. If it was eventually shown that a fairly constant level of penicillin in the blood was really necessary for full therapeutic effect the use of the oil-wax preparations might have to be considered. Only preparations occasionally failed to be absorbed and there was a localized tender induration three days after injection. He had not abandoned arsenicals and bismuth used in conjunction with penicillin, it was even possible that synergistic action existed between the two methods of treatment.

Whether or not penicillin passed the blood brain barrier, it was certainly capable of exerting considerable effect on the meninges and central nervous system when given by parenteral injection. In his earlier cases treated with penicillin he did in fact use the intrathecal route, but he had abandoned routine intrathecal injection in neurosyphilis, preferring intramuscular injection in adequate dosage, except in certain cases of tabes with severe and frequent lightning pains. Serological reactions particularly the Wassermann reaction, were often little affected by penicillin treatment, and would continue to show positive results long after the cerebrospinal fluid had become normal. This appeared to be an additional argument for following up the penicillin with bismuth therapy. His present method of treating tabes was to give an initial course of penicillin intramuscularly up to a total dosage of 4 or 5 million units. This was followed by the usual arsenical and bismuth therapy until the serological reactions became negative.

Penicillin in General Paresis

Dr W. D. NICOL mentioned 57 cases admitted to the Malan Therapy Centre at Horton, 42 of them cases of general paralysis of the insane, and the remainder tabes and tabo paresis and miscellaneous cases. Thirty of these cases were given a course of penicillin after malaria, 14 received penicillin only, and 7 received a subsequent course of malaria. The penicillin was administered intramuscularly in every case in a dosage of 300,000 units daily, in one injection, for fourteen days. One of the most striking clinical features was the physical and mental improvement in many patients—a phenomenon rarely if ever seen during malarial therapy. Most dramatic results were seen in patients who were confused and in poor physical condition. Penicillin would prove a useful adjunct to malaria, but only time would show whether it could supersede it. It was known that malaria in an established case of general

Marmite
in
Nutritional
Retrobulbar
Neuritis

For some years Marmite has been recognised as a preventive and curative agent in the nutritional retrobulbar neuritis found among certain native populations and lately encountered among P.O.W.s and internees in the Far East during captivity and also since their release.

Experience has shown that early treatment with Marmite will usually restore visual acuity and make complete recovery possible in those cases where irreversible changes have not already taken place. The efficacy of Marmite in combating this condition is ascribed to its high content of vitamins of the B group.

MARMITE

Vitamin Therapy —its uses and limitations

THE ANTI-HAEMORRHAGIC VITAMIN

Vitamin K is of considerable use to the physician, the obstetrician and the surgeon. Not only is routine antenatal administration becoming a practice to prevent haemorrhagic disease of the newborn, but treatment is under investigation for a variety of conditions in which low prothrombin values may occur—e.g., in hepatic disorders, necessitating a low fat intake, more particularly where surgical treatment is required—in digestive disturbances where fat absorption is poor and in some allergic conditions.

Synthetic analogues of Vitamin K are available as

SUPPORT WITH COMFORT

Abdominal Ptosis in all its forms can be reliably treated by the Curtiss Abdominal Support No. 1. It gives direct anterior posterior pressure but has no undue constricting effect on the lower abdomen and assures complete freedom of hip movement, in other words, it gives gentle pressure and firm support only where it is needed. Lasting comfort in wear is assured at all times by the high standard of workmanship and finish. This is one of the many types of Curtiss Products whose use is recommended by the Medical Profession.

CURTIS MODEL No. 1
R.T.M. ABDOMINAL SUPPORT

Introducing 'PENEUCIN'

TRADE MARK

BR. 110

PENICILLIN

ointment B.P.

PENEUCIN is supplied in tubes of 30 grammes each containing 500 units of penicillin (calcium salt)

Not that penicillin ointment B.P. is an official preparation we offer PENEUCIN — penicillin compounded with Eucenol. Anhydrous our well known brand of Ung. Alcoh. Lanæ B.P.

PENEUCIN can confidently be prescribed whenever penicillin ointment B.P. is indicated for the treatment of staphylococcal and streptococcal infections of the skin e.g. Syco, barbae, impetigo, secondary infected eczema.

paralysis of the insane should be accompanied by some additional form of therapy, and it might be that penicillin would be the optimum choice

Cerebral Oedema

The French visitors opened a later discussion on cerebral oedema. Prof ALAJOUANINE spoke on cerebral oedema in arterial hypertension.

The acute and temporary form, he said, was not the more frequent, but it had the more distinctive features. The clinical picture resembled closely that of subarachnoid haemorrhage. The patient first suffered from an intense headache, then vomiting occurred, with failure of visual function, and, sometimes gradually and at other times suddenly, there was unconsciousness, developing into deep coma. Several of his patients had had a number of attacks of cerebral oedema, one had had ten attacks in two years. In some cases there was also subarachnoid haemorrhage, so that there could be a mixture of the two conditions.

The second type, the chronic or permanent form of cerebral oedema, presented a different picture. Sometimes, but not always, it developed after two or three of the acute attacks, showing that there was a relationship between the two. The symptoms were those of pressure, which was demonstrated by headaches, vomiting and progressive drowsiness. This form of cerebral oedema had a bad prognosis. Sometimes hypertension and sometimes cerebral haemorrhage was the cause of death.

Dr DOUGLAS MCALPINE said that the subject of cerebral oedema had been rather neglected in this country by neurologists because the cases were usually admitted to hospital under a general physician. In a recent series of 18 cases the average age was 58. It was difficult to fit in the clinical picture with the conception of generalized cerebral oedema, but, as Prof Alajouanine had suggested, there were various grades and degrees.

Dr JACQUES LE BEAU (for M CLOVIS VINCENT) discussed cerebral oedema in neurosurgery. He said that, excluding head injuries, it was believed that compression of the brain stem might have something to do with the production of cerebral oedema, though it was not believed to be the cause. Prof GEOFFREY JEFFERSON, Dr J G GREENFIELD, and Dr A M STEWART-WALLACE contributed to the subsequent discussion.

ELECTRONIC HEARING-AIDS

At a meeting of the Section of Otology of the Royal Society of Medicine on May 2 with Mr H V FORSTER in the chair the design and application of electronic hearing aids was the subject of a paper by Mr E C NAYLOR-STRONG who demonstrated the components of these instruments and discussed their advantages and disadvantages.

Mr Naylor-Strong said that if certain minerals or salts such as quartz were submitted to mechanical strain of a very slight order an electric current of minute proportions was produced between the faces of the crystal. A crystal of quartz or Rochelle salt was attached to a paper diaphragm or the like. A sound wave falling on it would move the diaphragm slightly and so bend the crystal, producing electric currents so small as to be unable to activate any mechanism to produce sound unless magnified many thousands of times, hence the need for the valve amplifier. The amplifier must be capable of reproducing and magnifying faithfully each electric current in rapid succession and over all the necessary frequencies. It consisted of thermionic valves each connected to its neighbour by a set of electrical components.

Use of Audiograms

Hitherto the audiogram had been used as a measure of the patient's hearing loss and, to some extent, as an aid to diagnosis. It could also demonstrate the loss of certain pitches of sound, so that if it was desired to raise all the frequencies to the same level it could be shown that it was necessary to amplify some and leave others as they were or amplify them to a different degree. A hearing-aid which would enable the patient to hear all sounds equally was, so to speak, an amplifier which 'distorted' what it heard in a predetermined manner, the

'distortion' being the complement or reverse of the distorted sound heard by the deaf person.

The problem was, by studying the graph of the patient's hearing, to arrive at a judgment as to whether a particular aid would be of use to him. The complaints made by many patients had their origin in causes the effects of which the patients were unable accurately to describe. After analysing many complaints he had found that the telephonic or metallic effect of the hearing aid on a patient's hearing was due either to amplification at the wrong frequency or to over amplification in some part of the range. It was possible to make a suitable adjustment in many cases. The matter was not one purely of loudness of sound but rather of the part of the sound which should be amplified in order to transmit it naturally to the wearer of the aid. It was comparatively easy to fit a practicable hearing aid in middle-ear defects, whatever their cause and also in cases in which there had been a radical mastoid operation or any other surgical treatment which had removed or bound down the small bones.

What type of earpiece should be fitted in a case of otosclerosis? Here bone conduction was good and preponderated over air conduction, so that it might be supposed that it was better to use a bone conductor than an air conductor but he gave reasons why this was not so. Bone conductors did not reproduce the high notes to the same extent as did air conductors. Some patients could hear equally well with bone or air conductors, in such cases the bone conducting fitment was less necessary.

The results of experiments he had carried out showed that the frequencies which should be relied on in order to get intelligent speech were 512 to 2096, or perhaps 3500. The loss which could be allowed while at the same time reasonable hearing remained was about 30 db on the average, if the frequencies could be raised between the stated limits to a loss of only 20 db the patient would probably hear with an aid. Taking 30 or 40 db as an arbitrary line the lower the frequency at which hearing loss took place, the more difficult it was for an aid to be fitted. In most people over forty years of age there was a loss of high tones—the commencement of nerve deafness. The greater the loss of high tones and the earlier on the frequency scale it occurred the more difficult it was to use the electronic type of aid and ultimately there came a time when no hearing aid could be fitted. The difficulties in such cases were those of overall amplification as the gain from the hearing aid increased so did the internal noise level and these patients were most susceptible to the heterogeneous frequencies of background noise produced in the instrument by thermal agitation in the valves or by other electronic causes. This was a matter upon which research was still proceeding. Another difficulty arose from the frequency response of electric aids. Their size and limits made it virtually impossible for their cut-off to be sharp. Although the responses might be varied, some unwanted tones always came in because of the heterodyne effect of sound of varying frequencies.

Mr Naylor-Strong then showed a series of audiograms depicting successful cases and also failures. All the results shown were from tests he had himself conducted with the audiometers and measuring instruments made in his own laboratory. In conclusion he ventured the opinion that when the Government issued to the public hearing aids of electronic design there would be little that was revolutionary. It seemed highly probable that the designers would confine themselves to well tried principles and produce aids similar to those exhibited to the Section.

In the course of a brief discussion Mr EMERY MARTIN expressed concern for the elderly deaf patient with lower tone loss insufficient to preclude background noise so that hearing would be improved by increase of the upper tones though with a loss of 50 db at 4096 and almost complete loss at 7000. If fatigue resulted in permanent deafness the provision of an aid would cut out that person's hearing wherever it was not supplied with an aid, he might be able to hear by means of an ear trumpet. Mr NAYLOR-STRONG agreed that there was need for more research concerning the tiring or fatigue resulting from hearing aids. But he wondered whether any patients had been heard to say that they heard worse after having been fitted. If the aid was properly adjusted he could not agree that it would make the hearing worse.

Correspondence

De Morgan's Spots

SIR—Capt A R Murison and his fellow investigators on the above subject (May 10 p 634) remark that the literature on these ruby spots is extremely meagre. May I suggest that the reason is that most of those who have taken any interest in the subject and have looked for these spots in various morbid conditions have come to the conclusion, as I have, that almost every adult person, regardless of the state of his health, has one or (mostly) more of the spots on his body. I feel sure that Sampson Handley and all other surgeons attach no importance to their presence in regard to the diagnosis of cancer. Doctors who examine patients with degenerative cardiovascular conditions have doubtless found them constantly present, and so with psychiatric and other specialists. Personally I have found one or more present in every adult and even some children in whom I have taken the trouble to look for them. An adult without any must indeed be a *rara avis*.

For a more exhaustive statistical study of the subject I would propose that in every adult case the whole of the body (not merely the greater portion) should be examined. If patients and others were assured that there was absolutely nothing to fear from their presence, they could be left to examine most of their own skin, and in this way a fairly reliable statistic, with relatively little trouble, could be reached. I wish some archaeologically minded doctor, in his spare time would take the trouble to search the old treatises on the detection of witches in order to ascertain what the professional "witch finders" thought of the presence of ruby spots—I am etc,

London W 1

F PARKES WEBER

Physical Health of Children attending Day Nurseries

SIR—I was interested to read Dr Margaret E McLaughlin's account (May 3 p 591, and May 10, p 631) of the physical health of children attending day nurseries especially with reference to the measles epidemics. During the months of February, March, and April of this year there was an outbreak of measles in my district. Most of these cases originated at the day nursery, in all I had seventy cases. At the beginning of the outbreak the children were attending the nursery up to the appearance of the rash and only during the latter end of the outbreak were they sent home when the cough and rhinitis were present.

I should like to make a few comments on the complications of measles. I had three cases of bronchopneumonia, occurring at the latter end of the first week and beginning of the second week after the rash appeared, which responded favourably to sulphathiazole. I also had about half a dozen cases of otitis media, occurring in the second and third weeks, three of which had to have a paracentesis tympani done. The rest resolved at the early stage with sulphathiazole. Finally I had six cases of conjunctivitis, occurring in the first week. These were the result of treatment by the mothers, who washed the eyes with various solutions from milk to boracic lotion. It is interesting to note that in this district washing the eyes out with milk is a common and accepted practice—I am etc,

Sheffield

I GOTTLIEB

SIR,—The difficulty about articles such as those by Dr Margaret E McLaughlin in the *Journal* of May 3 (p 591) and May 10 (p 631) is that others are liable to draw more definite conclusions from them than do the authors who are aware of at least some of their limitations. You state in your leading article on the subject that her results are "clear cut and striking". They are certainly striking, but it is not so clear whether they are clear-cut. One of the most striking things about them is that the only accurately measurable criterion which she used in her comparison of a group of nursery children with a group living at home—namely the weight—gave results favouring the nursery group. The remainder of her material was based entirely on subjective impressions which are so often misleading. It would appear also that she did not even have the advantage in making the comparison of not knowing to which group a child belonged. It is now generally recognized that for any

scientific purpose in work of this kind it is essential that the examiner should not know to which group an individual belongs otherwise the result may merely reveal an unconscious bias.

It is clear from what Dr McLaughlin herself says that her two groups are derived from different classes of the community doubtless with different income levels. In addition so far as one can judge from her article, she does not allow for the fact that infectious diseases, which she found more frequently in the nursery group, are more readily diagnosed by trained nursery staff than by parents. It is a matter of general agreement that such remarks as "general condition good, satisfactory, etc." are of very little value for scientific purposes, since different observers differ widely in their impressions, and even the same observer will report very differently on the same group examined after an interval. This criticism applies to all the criteria of health except weight, used in this investigation.

Desirable though it may be, therefore, accurately to assess the effect on health of the nursery environment, and important though it is to minimize infection in our new nurseries, the present investigation does not afford the opportunity for such accurate assessment and must not be used as the basis for a illogical campaign against nursery provision—I am etc,

Orpington Kent

BRIAN H KIRMAN

Acid Drinks and Sulphonamide Therapy

SIR—Dr Petronella Potter (May 10, p 654) raises an important opinion in regard to the administration of "acid drinks" during sulphonamide therapy which if accepted is bound to cause a great deal of unnecessary harm and will actually incur the very danger of renal complications which she is so keen to obviate. Apparently it is still not realized that the organic acids used in these drinks—e.g., tartaric and citric—are those which are metabolized in the body into carbon dioxide and water and that any basic element present in the fluid—e.g., sodium or potassium—is freed to form an alkaline solution. For example, imperial drink contains 0.08% free citric acid and 0.46% potassium tartrate, and I think it is possible to cause an alkalaemia on sufficiency of this drink alone.

I would like briefly to recapitulate the value of giving these acid drinks. (1) By their flavouring value they greatly help the patient to assimilate large quantities of water. (2) The acid flavour stimulates salivation and therefore helps to keep the mouth clean—a very important consideration in febrile patients. (3) They aid alkalization. (4) They have caloric value because of the contained sugar. Therefore the statement that "all fruit drinks (and presumably acid fruits) must be forbidden has been mistakenly applied, and it should be known that these drinks are still valuable as an aid in the nursing and treatment of febrile patients—I am, etc,

Neiley

LEON RADCLYFFE

SIR—Dr Petronella Potter's letter (May 10 p 654) condemning the administration of fruit drinks to supply the extra fluid required in sulphonamide therapy fails to take into account the fact that the natural fruit acids undergo oxidation in the human body and their acidity is destroyed. To quote from Dr V L S Charley's recent article in *Chemistry and Industry* 1947, 19, 221, on "The Nutritive Value of Fresh Fruits and Fruit Juices": "The acids in fruits are very largely composed of citric, tartaric, and malic acid. These are metabolizable and are used in the body as a source of energy. The ash constituents are largely composed of basic materials, and consequently their ultimate effect is to make a contribution to the alkaline reserves of the blood and urine."

The use of such drinks should not therefore be condemned on the evidence submitted—I am, etc,

Widnes Lancs

R A GREGORY

Groundnuts in East Africa

SIR—The *Journal* of March 8 has just arrived, and I must comment on the leading article entitled "Groundnuts in East Africa" (p 301). No credit was given to the United Africa Company Limited, who submitted the original plans to the Secretary of State for the Colonies and Minister of Food substantially the same as have been adopted, and, according to the official Tanganyika Territory Government pamphlet, *The Groundnut Scheme*, the proposals "had been worked out in

some detail" The proposals as submitted were "considered of sufficient importance and promise to require a thorough investigation on the spot," and this led to the immediate dispatch of an official mission This puts in their right aspect your words, 'this long sighted scheme of the present Government,' who, though showing most commendable speed in putting the scheme into immediate effect to catch the 1947 planting season, were not the originators—I am, etc

Shiwa Ngandu N Rhodesia

C M PHILLIPS

Medical Certification

SIR—I gave a certificate on behalf of a patient, whom I have attended for years for a chronic condition, to enable her to make a request for extra money to go to Aix-les-Bains for special treatment, which she was accustomed to have before the war with considerable benefit This certificate was sent to her bank, who replied that their foreign department had discussed the matter informally with the Bank of England, who stated "that the certificate supplied is not sufficiently informative and must cover the following points (1) Age of applicant (2) Nature of complaint from which the applicant is suffering (3) What treatment has been given and with what result (4) Why it is considered necessary for applicant to leave the United Kingdom for further treatment (5) Why Aix-les-Bains has been selected (6) Duration of stay recommended"

I ask you to publish these bare facts as I should like to hear the opinions of my medical colleagues It would appear that a medical principle of some importance is involved in such a demand, which the Association might consider and take action with the department responsible As far as the patient is concerned, she is naturally indignant that her age and details of her general health should be in this way made known to the bank officials—I am, etc,

London W 1

MORTON SMART

SIR—With State medicine almost upon us, and with it presumably an enormous increase in form filling is it not time for representation to be made for the simplification of forms?

In the case of infectious diseases surely it would be sufficient merely to state the number of fresh cases which have occurred each day I cannot believe that the person's age, sex, or exact address are of any practical importance in diseases such as measles and whooping-cough when the public health authorities do not have to be called in

I suggest that a printed form as follows is all that is necessary

"I have this day diagnosed fresh cases of measles whooping cough Signature address"—I am, etc,

Newport Pagnell Bucks

A A CLAY

Basic Salary

SIR—Those of us who have now a well-established practice can no doubt view with equanimity the prospect of a salary based on capitation fees As one who has in the past fallen into most of the traps which beset the unwary (or he trusting) in general practice, I think this attitude is just the icme of selfishness Have these protagonists of a capitation fee only ever tried to start a practice from scratch and found what a soul destroying business it can be?—unless of course they happen to have been made in the image of Midas

These generous souls (made in the same mould no doubt as Dr J A Jamieson (March 29, p 425)) are the ones who talk so often at B M A meetings about their principles Let them be compelled to scrape together a living from this kind of practice and they will then perhaps learn the burning truth of Mr Micawber's elementary economics—I am, etc,

Hove Sussex

G I, DAVIES

Infant Deaths

SIR—The article by Dr J Tudor Lewis (Dec 14, 1946, 893) and subsequent correspondence (Dec 28, p 1006, and an 18 p 114) draw attention once more to the all important subject of infant deaths I have just picked up 34 months' issues of the *B.M.J.* and I write at sea, some thousands of miles from home, so it is likely that other letters will have appeared

long before mine reaches England, I would, however, like to make some observations

Dr Lewis's first point is the question of liaison between hospital and home In my opinion the 'family doctor,' if such a person is to exist in the future, is the ideal and possibly the only satisfactory liaison officer If he does not actually deliver the woman in the maternity home or hospital, he should whenever possible take an active part in supervising and advising her on her own health and the care of her baby before she is sent, or has permission to go, home He is the one person in a position to judge her ability and to assess her domestic difficulties Dr Lewis's article appears to be written entirely from a "public health" or "State medical" point of view—private practice and choice of doctor have ceased to exist.

I agree entirely with the comments of Drs I M Harkness and J B Cochrane (Jan 18, p 114) on the discharge of the five cases noted What terribly tragic and pathetic reading is provided by the record of Dr Lewis's seven cases! All in my opinion were discharged from hospital far too soon Even to good homes with more than average facilities it is asking too much for an enfeebled anaemic woman to undertake household duties and the care of an undersized puny infant 10 days after confinement The two children in Case 1 after one triplet had died, and weighing only 4 lb 2 oz. (1.87 kg) at birth, were kept in hospital only four weeks and two days The remaining cases were discharged to unsatisfactory conditions after only 10, 15, 10, 10, 9, and 9 days in hospital, respectively—totally inadequate periods either to stabilize the babies or to let the mothers recuperate And what exactly is meant by 'poor mothering'? Poor mothercraft can scarcely be blamed for the enlarged congenital heart in Case 2 Dr Lewis's fourth clause under 'Conditions Affecting the Mother' is 'Maternal inefficiency, poor mothercraft and homcraft, lack of parental responsibility How much of this so-called 'poor mothercraft' I wonder, is due to alienation or frustration of mother instinct' by the inefficient teaching of modern scientific "rule-of-clock methods?"

I have not the least idea of how babies are wrapped or nursed in any of the hospitals under Dr Lewis's eye, but I would like to refer to my two letters concerning infant deaths in your issues of April 14 and June 2, 1945 (pp 529 784) Is it possible that when a baby is leaving an institution the parting instruction to 'keep him warm and on no account allow him to catch cold' may be the sentence of death to be executed by the relatively strong hands of the anaemic anxious and worrying mother? Lacking in "mothercraft perhaps but doing her best to carry out instructions and possibly trussing up her infant with its arms secured against the body thorax compressed and the feeble spark of life all but extinguished

I have seen no correspondence confirming the suggestion expressed in my two letters No doubt the point made is too obvious It is still argued that wrapping babies with their hands in their groins does not restrict their breathing It only needs to be tried without even fastening the shawl With arms in that position it is impossible to fully inflate the lungs, then atelectasis pulmonary congestion, bronchitis, bronchopneumonia and the onset of every other respiratory infection are favoured I also think that digestive troubles, difficulties with feeding and marasmus are further complications of this method of wrapping All are conditions from which young babies so frequently die I am told that babies are swaddled in the manner about which I have written at one of our great teaching hospitals Can it be that these experts leave some freedom of movement and do not over tighten the wrap but that the pupils who have seen no ill-effects follow have not grasped the real technique and do not realize how much force is used when winding round and tucking in the wrappers of their rigid and tidy little parcels? The necessity for this free movement allowing full expansion of the chest should be demonstrated and very emphatically insisted upon when instructing the inexperienced mother, who will have the subsequent care of the babe in her own hands Fortunately most mothers are very gentle and afraid of handling their tiny offspring so that they are less liable to swaddle them with homicidal firmness

The special care of weakly premature babies is now well understood by the modern nurse and these for a time at least will probably escape tight wrapping Possibly overheating in electric incubators is a very real danger unless a reliable

the-mostatic control is fitted. Presumably a baby suffering from artificial heart-stroke would have the symptoms of dehydration fever and the cause of death would be 'prematurity'. Too great a weight of blankets on the infant's cot may possibly be a cause of fatigue of the respiratory muscles—and death. The zealous harassed but inexperienced mother should be warned of this risk. Is the danger fully realized?

Though as already stated, I have not yet seen in print any expression of approval of my suggestion to have this matter thoroughly and conscientiously investigated obstetric specialists in centres in this country and as far afield as Australia have expressed their complete agreement with my remarks. The surprise and disappointment of being ostracized on account of these letters by some with whom I had worked most happily for many years have been compensated by the (to me) unknown

feckless, anaemic and frail little woman living under slum conditions, who had seen an extract of my letter in the lay Press, telling me that she had had no further trouble with her ailing baby after heeding the suggestion and abandoning the tight wrapping she had been taught.

Much of this may seem irrelevant as far as Dr Lewis's article is concerned but as the object of all of us is to save these precious lives I appeal once more to all doctors and nurses to satisfy themselves beyond all doubt that the infants under their care are not being slowly suffocated in the way described—I am etc

Huddersfield

S H WADDY

Periarteritis Nodosa

SIR—I was interested in Dr L. M. Shorvon's case of periarteritis nodosa (May 3 p 601). The difficulty of making this diagnosis during life lies in the diversity and the frequently changing character of the physical signs and symptoms in this condition. But it is just the great variety of the clinical picture—e.g., fever of the remittent type, tachycardia, polyneuritis, polymyositis, albuminuria and cylindruria, asthmatic attacks with bronchitis, hypertension, and leucocytosis with blood eosinophilia—which is suggestive of periarteritis nodosa. The conception of periarteritis nodosa being the result of an extreme degree of vascular allergy has found wide recognition in recent years. It therefore seems doubtful whether this condition represents a disease entity but rather belongs to the wider group of diseases caused by the anaphylactic hyperergic reactions—e.g., Loeffler's syndrome, angioneurotic oedema, tropical eosinophilia, and probably rheumatic fever. The principal difference of these conditions lies in the intensity and extent of the vascular involvement. In a recent publication of two cases of periarteritis nodosa (A. Elkeles and L. E. Glynn, *Brit J Radiol* 1944, 17, 368) we showed in serial radiographs of the chest the occurrence of transitory infiltrations in the lungs during the early stages of the disease. These were later superseded by persistent and progressive damage to the pulmonary vessels and bilateral pleural effusion. The presence of transitory as well as persistent and progressive changes in the lungs, with concomitant blood eosinophilia and the severe clinical picture made a correct diagnosis possible during life. Transitory pulmonary infiltrations and blood eosinophilia are also met with in Loeffler's syndrome but here the clinical picture is characterized by a mild course, and the lung infiltrations usually disappear completely within a few days, although in rare instances migratory pulmonary lesions may persist for several months.

In contrast to the striking radiological findings, physical signs of the lungs in Dr Shorvon's case and in our cases were scanty and even absent. That is why little attention has been paid so far to the pulmonary changes in this condition which, however, as shown by serial x-ray examination, may provide an important clue to this notoriously difficult disease—I am, etc

London W 1

A ELKELES

Heroin and Pethidine during Labour

SIR—I would like to express appreciation of the scholarly paper by Miss Josephine Barnes (April 5 p 437) on the use of pethidine in labour. Pethidine is certainly a safe drug to use and has many advantages. It has one very serious disadvantage, however, and that is that its action is unreliable. In Miss Barnes's series good analgesia was obtained in only 55% of

cases, a figure in accord with my own much smaller experience of pethidine.

There is one drug, however, which is vastly superior to pethidine, and that drug is heroin (diacetylmorphine hydrochloride). In analgesic effect heroin is much more powerful than pethidine, and its action is very much more reliable. When properly used it does not interfere with the normal course of labour and, as I have already shown in a previous communication (*Jan & Feb 1944*, p 59) it can be safely given in full doses at any time during labour.

With experience one varies the dose according to the type and frequency of the contractions and the degree of dilatation of the cervix, but as a general guide one would say that 1/6 gr (10.8 mg) should be given when the cervix is three fingers dilated and further 1/12 gr (5.4 mg) just before full dilatation. If the cervix is almost fully dilated or the second stage has already commenced when first seen one would give the full dose of 1/6 gr (10.8 mg) straight away. It is important not to give heroin too soon in the first stage or else uterine action will be damped down. In this respect heroin differs from pethidine, which can be given earlier in labour. In those cases where the contractions are weak and some degree of uterine inertia is present I prefer to give pethidine rather than heroin.

When heroin is given in adequate doses, supplementary anaesthesia at the end of the second stage is not always required. When it is deemed necessary, a little chloroform or gas and air can be administered. For certain cases, particularly breech delivery, I find pudendal block very efficacious.

There are of course other aspects of the prevention and relief of pain in labour apart from the administration of analgesic drugs and it is important not to neglect them. For example, there is the overcoming of fear and tension, and there are those measures designed to promote flexibility of the pelvic joints during pregnancy. The actual method which one employs to relieve pain in labour is probably of secondary importance. What is far more important is that everyone should master some method and apply it conscientiously. There is, unfortunately, far too much apathy and indifference among those who undertake maternity work. To make no attempt to relieve pain in labour, or to make only a half-hearted attempt, is a sign of slackness and a public confession of mediocrity—I am etc.

Troon Ayrshire

JAMES ROSS

Artificial Insemination

SIR—In the answer to a correspondent's inquiry about the technique of artificial insemination ("Any Questions," May 3 p 625) you conclude "Finally, attention should be drawn to the medico legal aspects of this procedure," and refer him to a leading article on the subject in the same issue. While conceding that the leading article was intended to cover only a special aspect of the subject, I feel strongly that the answer should have included an admonition about the psychological as well as the medico legal aspects. As your leading article points out the legal status of the procedure and its consequences are still beset by doubts, but even a lay person unacquainted with formal psychology can hardly doubt that serious psychological dangers threaten all those who accept artificial insemination.

It is the clear duty of doctors and psychologists to point out the formidable hazards to happiness and peace of mind which confront all who resort to this expedient. The vital human factors, which should outweigh all other considerations, have received a minimum of attention or have been ignored as matters of small moment compared with the technical problems involved.

It is a fact that couples who request artificial insemination constitute a cross section of psychological types. It is more over by no means easy for even an expert psychologist to predict with confidence that any couple will not eventually experience strong emotional reactions which may become increasingly intense as the years pass. The manifold and ineradicable psychological difficulties which might wreck the lives of the woman who accepts A.I.D. her husband and the "test tube" child will be evident to anyone who gives the subject a moment's thought. However eagerly she may have resorted to the method in her desire for a child the woman sooner or later is likely to experience a vague feeling of dissatisfaction with herself—what we might almost term a sense of sin, of

or unwholesomeness. In spite of herself she is almost to indulge in morbid musings about the unknown father of her child and she may tend to grow away from the husband, played no part in the deepest experience of her life. The band, whose self-esteem was dealt a shattering blow by the revelation of his sterility, cannot help but consider the child a constant reminder of his "inferiority," and in time he may come to hate it and hotly to resent the attention which his wife lavishes on it. The child, an ambiguous figure at birth, will be the most pitiful victim of these and other devastating and uncontrollable emotional consequences, which, to date, have received far too little consideration.

In the past I have administered both types of artificial emination, but as a result of experience and reflection I would not now take any case except one in which the husband was a donor. I think it essential that all doctors, whatever their views should present the psychological objections to their patients in the strongest terms—I am, etc.,

London W 1

EUSTACE CHESSEY

Complete Abortion without Initial Vaginal Bleeding

SIR—The following case is of interest on account of the rarity of abortion occurring without warning uterine bleeding.

The patient, a para-3 aged 28 was seen in her own home on account of severe upper central abdominal pain of four hours' duration. The pain was colicky in nature, did not radiate, nor was it accompanied by vomiting, but was made worse by movement and deep breathing. Her personal history revealed the fact that she had been severely constipated for eight days and that she had not had a "proper" menstrual period for three months, although there had been some staining at the usual date of her period during this time. There was no history of previous abdominal colic.

On examination she did not look ill, temperature was 98° F (36.7° C), pulse 100 and there was generalized tenderness over the abdomen most marked in the right iliac fossa but without definite guarding. The rectum was loaded with hard faecal masses. Vaginal examination showed the uterus to be enlarged consistent with a 12- to 14 week pregnancy. There was no blood on the examining fingers nor on the vulva. The urine contained no gross abnormalities nor were there any physical signs in the chest.

Two soap-and-water enemata were given with good result and some relief of pain. Conservative treatment and observation was considered advisable and suitable. Next day the pulse had settled to 80, but there was still tenderness in the right iliac fossa, and the rectum was still loaded with faeces. Two further enemata were given with good result, so that the patient was free from pain on the third day.

On the fourth day of her illness the patient experienced a recurrence of mild colicky generalized abdominal pain indicating, as she thought, the need to use the bed pan. Into the latter she passed a complete foetus of about 14-weeks size, along with a small blood clot. This blood was the only haemorrhage seen during the numerous visits paid to the patient. Recovery has been uneventful following curettage, when only a small amount of blood clot was removed—I am, etc.,

Child Guidance

SIR—Dr Ian Skottowe in his letter (May 3, p 616) speaks of (1) "the unnecessary confusion that there is on this subject" (2) "mental illness in children." The use of the term "mental illness" doesn't help much.

Most of the authorities are not agreed. The Association of Education Committees have recently stated that the educational psychologist should be in charge of child guidance clinics and not the psychiatrist. If we do as Dr Skottowe suggests and "leave the matter there" the education departments with the psychologist in charge of the "centre" (and the psychiatrist an indispensable lackey) will have control of the "treatment" of most maladjusted children delinquents etc. while the medical department will be expected to deal with what? Mental illness? Psychotics amounting to about 4% of children requiring psychological treatment? Or just the rejected enuretics and some encopreses?

In the meantime the Ministry of Education expects the medical department of the local authority to certify on the appropriate form the fate of educationally subnormal pupils (a definition of which is based not on the I.Q., by the way, but on the standard of achievement in the basic subjects). What sort of topsy turvy chaos will exist? Dr Skottowe may or may not know that in one of the Home Counties the educational psychologist is arranging all the child guidance clinics through the education department. If the medical department sets up "mental illness" clinics there will certainly be two administrations dealing with the children requiring psychological treatment.

I repeat my previous contention—namely, that where the school training (with the educational psychologist advising the chief education officer) has failed to prevent a child reaching a child guidance clinic or centre the child's problem is both psychological and clinical—psychological for obvious reasons which nobody denies and clinical because in most cases there is a parental problem which should not be dealt with by a lay worker. For that reason all psychological misfits which the schools cannot deal with should be in the first instance directed to the school medical department. I am forced to this conclusion not through any motives of 'will to power' for my faculty but sincerely in the belief that the educational psychologist although far ahead of the psychiatrist in the technical armamentarium and skill of his profession is nevertheless quite unfit to appreciate more than the surface of the parental problems. If by mental illness Dr Skottowe (and for that matter the Ministry of Health too) means all psychological misfits then Dr Skottowe and I have no argument between us.

I disagree altogether with his dislike of the syntax of the term "child psychiatrist." He is just allowing his imagination too much scope. Is a child lover necessarily a minor? A bird watcher an animal? Or a rabbit hutch a rabbit?—I am etc.

Nicotinamide and Diabetes Mellitus

SIR—I was very interested to read Dr H J Wade's article on nicotinamide and diabetes mellitus (March 29, p 414). I have been working on the subject for the past year and have published a preliminary report on thirty cases in the *Journal of the Royal Medical Association of Egypt* 1947, 30, 29. I found that 60% of the cases of diabetes mostly in the mild and moderate group and a few in the severe group do well on this form of therapy as shown by the sugar-tolerance curves. Those that do not show any or only slight response are the juvenile diabetics, and some of each of the above groups mostly the severe ones. Even in these cases the insulin requirements may be decreased.

I would like to point out that I used the same dosage as Dr Wade, but that it takes four to six weeks to show any appreciable response and up to six months to show optimum response. I suggest that Dr Wade did not follow his six cases sufficiently long and that their number is inadequate for any conclusion—I am, etc.,

SAID M TALAAT

Safety in Electric Convulsion Therapy

SIR—The letter from Dr R A Sandison (April 26, p 579) is very important to me and, I hope to many others. It could reopen the long and somewhat acrimonious correspondence which you received about anaesthesia and it emphasizes the dangers of elaborating what should be a simple procedure. I have been forced by circumstance to be an anaesthetist and am by inclination a psychiatrist. In both of these specialties I feel that the "human" element is disappearing, and the patient is now becoming a piece of physiological apparatus.

Some time ago I read in the *Journal* of a Service woman who had died during an operation for an "interval" appendix. She had received thiopentone to prevent her being upset by a spinal anaesthetic which had to be supplemented by gas and oxygen. One was left with the impression that any feeling about the summation of all those anaesthetics having been connected with the cause of death had been satisfactorily rationalized.

Likewise in ECT I have lived with 600 epileptics for five years and if one worried about everything that could happen to them (but yet so rarely does) one would have them permanently in bed under light thiopentone and *d* tubocurarine chloride

I only want to ask this question of my psychiatric colleagues (except Dr Sandison, who is on my side) If you had to have ECT, wouldn't you like to have the button pressed *first* and an adequate routine laid on to prevent your injury and/or demise after you were 'out,' or would you, like me, probably die of fright before you could be resuscitated, when you had (1) been buckled into your canvas jacket, (2) had your straps secured, (3) had your leather headband put on, (4) received your injection/injections or any other refinement calculated to prevent your receiving an injury which may never happen if the simplest method is used, and would be better than dying of (a) fright and (b) medication, anyway?—I am, etc.,

J MACKEY CRAWFORD

Folic Acid

SIR—I have been interested in the leading article (May 3, p 604) concerning folic acid as a therapeutic agent, and perhaps I may be excused for bringing to your notice a single case of subacute combined degeneration of the cord which has recently been under my care

The patient, a male aged 55 years when I saw him first had been suffering for three months with loss of power in the legs, unsteadiness, marked sensation of cold spreading up the legs when standing, tingling, and numbness. On examination the findings were those of a spastic ataxia, the blood that of a pernicious anaemia. He could not stand without support and walked only with help and with a markedly spastic and ataxic gait. Intensive liver treatment was started on March 20 and continued for three weeks, with marked improvement in the blood state but only slightly in the nerve condition.

I then administered folic acid 10 mg daily and gave a maintenance dose of liver weekly. Within a few days a marked improvement took place and has continued since, reaching a climax to-day, when I saw him walking, using a bicycle as a partly moral and partly physical support a mile distant from his home—I am, etc.

CECIL L FORDE

Shortage of Nurses

SIR—Dr R. Howell Roberts suggests (May 10, p 655), that professional examination of "orderlies" for higher rank in the three Services should be brought into line with civilian standards. Surely, Sir the boot is on the other foot! Sick berth ratings passed for higher rates in the Navy, their opposite numbers in the other Services, and the VADs who have had similar training and experience during the late war are recognized as nurses fit to be entrusted with the care of the sick in the Services.

If the General Nursing Council could forget its obsession with examination standards and its own importance it might make a real contribution to the serious national shortage of nurses by accepting these ex-Service men and women as qualified nurses and granting them State registration on their discharge from the Services, with recommendation for such registration by the relevant Service medical authorities.

No man or woman after several years of responsible nursing will consider beginning again to "train" for the State Registered Nurse examination under existing rules, but many are experienced nurses well worthy of inclusion in the Register forthwith. The General Nursing Council must get down from its high horse and face the facts—I am, etc.

SURGEON COMMANDER, R N

Congenital Malaria

SIR—Dr P G Preston's letter (March 29 p 422) impels me once more as on a similar occasion last year, to attack the complacency of reporters of alleged instances of the above alleged syndrome. As a much examined student from whom examiners require much accuracy of statement and quotation, I deplore the almost universal failure of reporters in this field to present their alleged facts, which may be facts indeed, in

anything remotely approaching a scientific or factual manner which can readily be understood and accepted.

To quote from the letter under "deploration" 'blood' was taken on three consecutive days following its birth. Were these the first three days after birth, or the 8th, 9th 10th, or the thousand and first, etc? And again "out of 700 patients examined 40 mothers were found to have malaria parasites in the placental blood, and two infants." This second phrase gives no factual information and is capable of various interpretations, among them a comical one, which is, however, relevant to my argument—i.e., that twin infants were found in the placental blood. The latter interpretation calls to attention one of the many factors which have to be considered and eliminated before a true bill can be presented for congenital malaria, that is, the possibility of post partum infection by placental or maternal blood through abrasions, the severed cord, or even the delicate mucous membranes of the infant.

As I contended on a previous occasion, few if any alleged discoverers of congenital malaria have advanced foolproof scientific evidence of their discoveries—at least, not enough to satisfy an advanced student—I am, etc.

Responsibility for Drugs Supplied

SIR—I would suggest an alternative to the "disturbing and crushing alarm" expressed in the medico legal article (March 29 p 428) at the prospect of practitioners' being liable to heavy damages for the possible damage done to their patients by new preparations recommended by drug-retailing firms. Instead should we not perhaps take it as a timely warning of the bad state into which our clinical medicine to-day is drifting? Did each of us do six or more years of intensive study to be led continually 'by the nose' by laboratory chemists and the large financial considerations that are behind the drug retailing firms? Why do we experiment on our patients on the advice of attractive pamphlets that litter our breakfast tables each morning?

I would suggest that it is chiefly due to two reasons which we might well try and rectify immediately. (1) The inability of the average overworked practitioner to attend refresher courses at least every two or three years. In consequence of this he is much too much a willing victim to the commercial drug concerns in a blind effort to keep up with the times. (2) If in our student years and in the medical literature thereafter disease was analysed and studied a *little less* and a positive approach to the natural health of body and mind synthesized and considered a *little more* then perhaps our impulse to be influenced by the often ignorant demands of our patients for useless bottles of medicine and possibly harmful injections would be changed to a bold, clear resolve to attempt to change and remedy some of the many bad habits of living and eating of our time.

The cycle of a healthy soil through natural composting leading to healthy, pest free vegetation and thence to healthy, disease-free animals has already been overwhelmingly scientifically proved after the artificial manures, chemical sprays, and injections had all lamentably failed. Man is an intrinsic part of that cycle, and the sooner that we use fewer bottles of medicine, sprays, and injections and help our patients back into that natural cycle of real health that the more progressive agricultural experts have already discovered and utilized so the sooner, among the many enormous benefits to mankind, will be solved the little problem of safeguarding our pockets from harm we may do our patients, because such a state of affairs will happily no longer arise—I am, etc.

H P KILSBY

William Blake Psychologized

SIR—It was only to be expected that, with the contemporary break-up of social organization, there should to day show itself a parallel tendency to mental dissociation, taking many forms and constituting the starting point of numerous serious psychopathies. Although personally unacquainted with William Blake's prophetic books, I am interested to read that the strange *dramatis personae* with their uncouth names in these poems represent symbolically a "disintegration" of the soul or uncon-

scious mind. It appears that a recent exponent of this poet's teaching, Mr W P Witcutt (*Blake a Psychological Study*), interprets him according to the system of C G Jung of Zurich, as a 'dissociated introvert, as one whose inner vision has become disintegrated into its "elements"—these elements then appearing as the "gigantic figures," spectral illusions,' etc., of his dreams and imaginative works.

But if this is possible of the individual's inner vision why not of his outer also? One recalls that the 'nature spirits' of folklore and the "minor deities" of polytheism in general have already been interpreted along these lines. Further according to this conception all these subsidiary divinities represent less a stage in an approach to monotheism than a lapse away from it, attributable to a slackening mental grip, a dissociation *a la* Pierre Janet. It will be interesting to note whether folklorists recognize the parallelism, the recognition should be illuminative both to them and to psychopathologists—I am, etc.,

North Queensferry, Fife

A J BROCK

Lectures from Edinburgh

SIR—Prof L J Witts has reviewed (May 3 p 602), under the above title, the third volume of the *Edinburgh Postgraduate Lectures in Medicine* which is published through a grant from the Honyman Gillespie Trust. As chairman of the committee which was responsible for the invitation to the lecturers and for the issue of these lectures in the *Edinburgh Medical Journal* from time to time and at a later date in book form, I would take exception to some of his criticisms, which show a lack of appreciation of the purpose and value of these publications. The reviewer it is true, pays a compliment to the thirty-two lectures which comprise this volume when he writes that they exemplify 'the high level of didactic teaching characteristic of the Scottish schools of medicine,' but he makes no mention of the fact that the lectures were all delivered by experts dealing with aspects of their respective subjects in which they were particularly interested and that, since they are replete with the lecturers' personal views, experience and original observations they are definite contributions to knowledge. The present volume and a fourth would have been published before now but have been held up by the paper shortage.

I may say that I do not agree with Prof Witts that the day of the published clinical lecture has passed, for personally I have derived much benefit and pleasure from the perusal of the clinical lectures published by some of our great clinicians. The clinical lecture affords, does it not, an opportunity to express and emphasize the art as contrasted with the science, an aspect of medicine which, as many clinicians will agree, often does not receive in our teaching nowadays the attention which it demands. Prof Witts makes no attempt to assess the value of the individual lectures. Indeed he finds this volume 'more difficult to read than any recently received volume.' 'It is difficult,' he writes, 'for any one reader to be interested both in the Control of Sepsis and in Delinquency, in the First Month of Life and in Prostatic Enlargement.' I agree that such diverse topics are not likely to appeal to the purist. On the other hand a volume of the kind is appreciated by the general practitioner who wishes to keep abreast of the times and by many others who attend these lectures.

I was personally responsible, and make no apology, for advising the Honyman Gillespie trustees to permit the utilization of their grant, according to the terms of which animal experiments may not be referred to, for the delivery and publication of these lectures, which illustrate some of the clinical activities of the Edinburgh School, nor shall I apologize for their subsequent publication in book form, which, I submit, fulfils a most useful purpose. Prof Witts concludes that "Only pious devotion to an *alma mater* would justify the purchase of these addresses." But even if this were so which it is not, for these volumes appeal to graduates of many other schools is not this a worthy motive? Is it not the case that both Bart's and Guy's to the staffs of which Prof Witts was I think, at one time attached, publish their *Hospital Reports*?—I am, etc.,

Edinburgh.

EDWIN BRAMWELL

POINTS FROM LETTERS

Heat and Certificates

Dr LINDSEY W BATTEN writes. Every new infringement of liberty, the almost daily 'thou shalt not,' the rare but not popular 'thou shalt,' trails after it a countervailing medical certificate. For the bureaucrat we are the indispensable mediator between him and the disillusioned elector softening and making just bearable the injustices and absurdities of his edicts, for the reluctant citizen of every social class and political party we are the dispenser of privileges, the annuler of obligations, the anaesthetizer of the pricking conscience. The pressure upon us to perform these functions is very great often it amounts to compulsion. Save in retirement there is no escape from acting as the universal unpaid arbitrator and referee in innumerable cases of *Rex v Smith*. Yet all this has no part in the Hippocratic Art, it is not for this we took to medicine, and the functions we perform are of the most dubious ultimate value either to the citizen or the State. The crowning absurdity has come in the demand for gas and electric fire certificates. Parliament has approved a law which the Government admits it cannot and will not try to enforce. Many members of Parliament have protested that it must be widely disregarded and every practitioner must know from his experience of the last four months that they are right. The thoughtless, the wasteful, the disgruntled will turn on their heaters whenever they feel cold, and no class has a monopoly of these folk. Without far clearer definition of the clinical conditions supposed to justify electric heat in England now I trust we shall all decline to give any certificate leaving Government and citizen to work out their own salvation.

"Ectopia Testis with Seminomatous Change and Torsion"

Dr A H BENNETT (Hartford, Cheshire) writes. With reference to the article 'Case of Ectopia Testis with Seminomatous Change and Torsion' which I communicated to the *Journal* with Dr D W G Shaw on Feb 15 (p 256), I have recently received from Dr John Burke, of Buffalo, New York, a copy of an article contributed by him to the *Zentralblatt für Chirurgie* 1948 65 2821, entitled "Stielgedrehtes intraabdominales Seminoma Testis." The case history is remarkably like our own, but it may be worth noting that he has furnished a quantity of bibliography, which I add, namely:

Bulkley, K., *Surg Gynec Obstet* 1913, 17, 703

Eisendrath, Daniel N., and Rolnick, Harry C. *Textbook of Urology for Students and Practitioners*, Philadelphia and London I B Lippincott 1930

Rea, Charles E., *Amer J Cancer*, 1931, 15, 2646

Young, Hugh H., and Davis, David M. *Young's Practice of Urology*, Philadelphia and London W B Saunders 1926

Association of Operating Theatre Technicians

Mr A WARNER writes. For many years in the larger hospitals in London, also in some other towns in the country, men have been employed as orderlies or theatre porters in the operating theatres.

Now a body of men with many years' experience in theatre work have formed an association under the heading of the "Association of Theatre Technicians," and many London surgeons and anaesthetists have offered them a backing, the idea being that in future anyone wishing to be employed in the capacity of a theatre technician shall have a course of training and instruction in the whole of theatre technique and will need to be thoroughly conversant with the working of the theatre its instruments, apparatus and the general procedure pertaining to the theatre. Information will gladly be given by the Hon Secretary, Mr A Warner, 56, Firwood Avenue, St Albans, Herts.

"Is it, Doc?"

Dr P K MURPHY (London, W) writes. Dr Stuart Warden's story (May 3, p 617) of his 18-year old patient who, when asked whether her bowels were regular, appealed to her mother, 'Are they, Mum?' was very, very amusing. But is it any less comic than his conclusion? We are asked to accept the incident as an overwhelmingly true summary of modern State education. Dear dear! Surely all it indicates is that no matter what system we adopt there will ever, unfortunately, be a mentally sloppy, half-baked few who cannot be relied on to know their acetabula from their elbows.

Retaining Fees

Dr P B CORBETT (Norwich) writes. At least three times this year I have been awaiting confinements which have been from two to three weeks overdue. This has been a great source of inconvenience as very important engagements have had to be abandoned. Lawyers have a refresher fee per day marked on their brief, is it not possible for us to adopt a somewhat similar course—a retaining fee for every day or week over the booked date?

Likewise in ECT I have lived with 600 epileptics for five years and if one worried about everything that could happen to them (but yet so rarely does), one would have them permanently in bed under light thiopentone and *d* tubocurarine chloride.

I only want to ask this question of my psychiatric colleagues (except Dr Sandison, who is on my side) If you had to have ECT, wouldn't you like to have the button pressed *first* and an adequate routine laid on to prevent your injury and/or demise after you were out, or would you, like me probably die of fright before you could be resuscitated, when you had (1) been buckled into your canvas jacket, (2) had your straps secured, (3) had your leather headband put on, (4) received your injection/injections, or any other refinement calculated to prevent your receiving an injury which may never happen if the simplest method is used, and would be better than dying of (a) fright and (b) medication, anyway?—I am, etc

The pressure upon us to perform these functions is very great, often it amounts to compulsion. Save in retirement there is no escape from acting as the universal unpaid arbitrator and referee in innumerable cases of Rex v. Smith. Yet all this has no part in the Hippocratic Art, it is not for this we took to medicine, and the functions we perform are of the most dubious ultimate value either to the citizen or the State. The crowning absurdity has come in the demand for gas-and-electric fire certificates. Parliament has approved a law which the Government admits it cannot and will not try to enforce. Many members of Parliament have protested that it must be widely disregarded and every practitioner must know from his experience of the last four months that they are right. The thoughtless, the wasteful, the disgruntled will turn on their heaters whenever they feel cold, and no class has a monopoly of these folk. Without far clearer definition of the clinical conditions supposed to justify electric heat in England now I trust we shall all decline to give any certificate leaving Government and citizen to work out their own salvation.

"Ectopia Testis with Seminomatous Change and Torsion"

Dr A H BENNETT (Hartford, Cheshire) writes. With reference to the article 'Case of Ectopia Testis with Seminomatous Change and Torsion' which I communicated to the *Journal* with Dr D W G Shaw on Feb 15 (p 256), I have recently received from Dr John Burke, of Buffalo, New York, a copy of an article contributed by him to the *Zentralblatt für Chirurgie* 1938, 65 2821, entitled 'Stielgedrehtes intraabdominales Seminoma Testis'. The case history is remarkably like our own, but it may be worth noting that he has furnished a quantity of bibliography, which I add, namely:

Bulkley, K, *Surg Gynec Obstet* 1913, 17, 703

Eisendrath, Daniel N, and Rolnick, Harry C. *Textbook of Urology for Students and Practitioners*, Philadelphia and London I B Lippincott 1930

Rea, Charles E, *Amer J Cancer*, 1931, 15, 2646

Association of Operating Theatre Technicians

Mr A WARNER writes. For many years in the larger hospitals in London also in some other towns in the country, men have been employed as orderlies or theatre porters in the operating theatres.

Now a body of men with many years' experience in theatre work have formed an association under the heading of the 'Association of Theatre Technicians,' and many London surgeons and anaesthetists have offered them a backing, the idea being that in future anyone wishing to be employed in the capacity of a theatre technician shall have a course of training and instruction in the whole of theatre technique and will need to be thoroughly conversant with the working of the theatre its instruments, apparatus and the general procedure pertaining to the theatre. Information will gladly be given by the Hon Secretary, Mr A Warner, 56, Firwood Avenue, St Albans, Herts.

"Is it, Doc?"

Dr P K MURPHY (London, W) writes. Dr Stuart Warden's story (May 3, p 617) of his 18-year old patient who, when asked whether her bowels were regular, appealed to her mother, "Are they, Mum?" was very, very amusing. But is it any less comic than his conclusion? We are asked to accept the incident as an overwhelmingly true summary of modern State education. Dear dear! Surely all it indicates is that no matter what system we adopt there will ever, unfortunately, be a mentally sloppy, half-baked few who cannot be relied on to know their acetabula from their elbows.

Retaining Fees

Dr P B CORBETT (Norwich) writes. At least three times this year I have been awaiting confinements which have been from two to three weeks overdue. This has been a great source of inconvenience as very important engagements have had to be abandoned. Lawyers have a refresher fee per day marked on their brief, is it not possible for us to adopt a somewhat similar course—a retaining fee for every day or week over the booked date?

Obituary

SIR FREDERICK GOWLAND HOPKINS, O.M. LL.D.
Sc.D., M.B., F.R.S., F.R.C.P.

The death of Sir Frederick Gowland Hopkins which took place at Cambridge on May 16, brings to an end the life of a notable man of science who has seen the subject he made his own become one of the most important of the biological sciences. Hopkins may be fittingly described as one of the "Fathers of Biochemistry."

Frederick Gowland Hopkins was born in 1861. His was a long life and was marked by successes in the academic world which it is given to few to attain. He was a President of the Royal Society and recipient of its Copley Medal, a Nobel

[Lafayette Ltd]

Prizeman and virtually the founder as well as the first professor of his subject at Cambridge. His achievements were recognized by the Crown by the bestowal of a knighthood and of the Order of Merit, by many foreign as well as British universities by honorary degrees, and by the bestowal of medals and prizes by learned societies.

The reality of greatness is never easily achieved, perhaps because adversity in one form or another is a reagent necessary fully to develop the finest shades of the human character, and until at least middle life Hopkins had to struggle against heavy odds. Lack of means is a common enough obstacle in the path of a man who wants to fulfil what he knows it is in him to fulfil. But financial difficulties, even had they been severe would have probably troubled Hopkins less than they would have many other men. Though his father died in Hopkins's infancy he was brought up by his mother and uncles in a comfortable home. His schooling was brought to an end at an early age as a matter of policy, not of necessity, and he was initiated at once into the insurance business. Though he was to be among the first scientists of his age, he had no formal scientific education at all. After a relatively short career as an insurance clerk he succeeded in gaining his point that he should be allowed to embark on a scientific career. It was almost decided that he

should go to Cambridge, when a chance and most unlucky lunch time conversation between one of his uncles and a Cambridge acquaintance resulted in the abandonment of the university project and his apprenticeship to a practising analytical chemist. The decision, made in all good faith, rested not on any financial or other objection to a university career but on the supposed superior merits of the apprenticeship as a means of scientific education. The chemist, in fact, used him solely as a junior laboratory assistant. A few attendances at a course of lectures at South Kensington (the only lectures on chemistry that he was ever to hear) were followed by the winning of a gold medal. This happened to coincide with the termination of his apprenticeship and was followed by his first salaried post with another analyst. On receipt of his first cheque from this employer—£40 for six months' work—he jokingly suggested framing it; his employer took the proposal seriously and supported it with warmth. About this time Hopkins was carrying on his first independent research on butterfly pigments—partly in the scullery of his mother's home at Enfield.

It was, fortunately, not long before he came in contact with and was taken as assistant by, Dr (afterwards Sir Thomas) Stevenson, then Home Office analyst. This involved him in medico-legal work of an interesting kind. It also brought him to Guy's Hospital. Imbued with the spirit of investigation, he won the Gull studentship and was able to continue his research along with his other duties. These came to include the teaching of pre-clinical subjects, and he determined to obtain a medical qualification. To do so he must first pass the London Matriculation, which involved the study of long forgotten Latin. Since his relations would have been deeply hurt had he shown himself unwilling to spend his evenings "socially," his only opportunity for doing this extra work was during the daily train journey between Enfield and London. This, however, appears to have been no great obstacle, and in almost the shortest possible time (he was once "ploughed" in midwifery) he obtained the London M.B. in 1894, together with the Gold Medal, having taken the B.Sc. four years earlier.

The next phase of Hopkins's career was clinical. His non-extensive, if unconventionally acquired, training in chemistry naturally directed his interests towards diseases of metabolism and problems of nutrition, and he began to acquire (probably without intending to do so, for he continued his Home Office work) a not inconsiderable consulting practice. He was also associated with one of the first laboratories which provided facilities for the general practitioner. It was among the Guy's out-patients that he was impressed by the fact that patients who apparently had enough to eat could still be badly nourished.

At this point came the great change in his career. Had he remained in London he would certainly have rapidly acquired a lucrative practice. Essentially humanitarian and sympathetic he would have been happy in his contact with patients. Michael Foster, however, then Professor of Physiology, invited him to Cambridge as lecturer in chemical physiology. He accepted. His task was not an easy one. His lectures and practical classes had to be created *de novo*. No apparatus to speak of was available. Michael Foster's death deprived him of much of the support on which he had counted. The lecturer's salary was almost nominal, and though a Fellowship at Emmanuel much improved his income it necessarily exacted a rather heavy toll of teaching work outside his own subject. His subsequent election to a tutorship at Emmanuel imposed even more duties though his personal qualities endeared him to his pupils. But during this time he built up his subject in the university—not always with helpful co-operation from his immediate colleagues—and carried out his pioneer work on vitamins and on the metabolism of muscle. His lectureship had meanwhile become a readership.

In 1914 the university created for him a Chair of Biochemistry. The post carried no stipend, but Hopkins was simultaneously elected to a Fellowship at Trinity and made Praelector of that college, a post carrying a salary but no duties. This relieved him of much of the burden of extra departmental work. It was neither the first nor the last time that the university's greatest college has come to its aid, and that of learning, in such a fashion.

As was natural, many tasks were laid upon Hopkins from without. He was one of the original members of the Medical

Progress in Hormone Research

* Available Shortly 'MIADONE'

dl 2 DIMETHYLAMINO 4 4 DIHENYLHEPTANE 5-ONE HYDROCHLORIDE

.... the new analgesic

'Miadone' is a recently-developed synthetic compound which sets an entirely new standard of analgesic potency Weight for weight, its analgesic potency is at least equal to that of morphine, it produces few side reactions, does not unduly depress respiration, and it may be given for long periods without diminution of effect

In clinical use it has been found of great value in the relief of all types of severe pain

*IMPORTANT Production arrangements are well advanced and ample supplies of the material are expected in a few weeks' time At present, supplies of the drug are limited to clinical trial

VITAMIN B₁ B.D.H.

The administration of Vitamin B₁ B.D.H. as a dietary supplement is important. For counteracting the early symptoms of vitamin B₁ deficiency such as intestinal hypotonus and anorexia, oral administration of tablets of Vitamin B₁ B.D.H. (1 mg. or 3 mg.) has proved a convenient method. For the treatment of such severe conditions as polyneuritis of pregnancy or of alcoholism and gastric abnormalities Vitamin B₁ B.D.H. may be given daily by subcutaneous or intravenous injection (ampoules of 25 mg. or 100 mg.) or orally (tablets of 10 mg. and 25 mg.) Further details are available on request.

ACID MILKS IN INFANT FEEDING

The wealth of buffer substances in milk results in the absorption of considerable quantities of acid in the digestive tract. In certain cases it is reasonable to give the infant the kind of nourishment which necessitates the least effort and controlled acidification offers a means of reducing demands on the secretory functions. In view of the varied nutritional needs of infants requiring acid milk the following range of products is available—

BEURLAC

A buttermilk in powder form useful for infants suffering from gastric disorders

PROLAC

Of approximate half cream fat standard but with increased protein as required in gastro enteritis

LACIDAC

HALF CREAM

An intermediate grade for less severe cases and for graduation to normal feeding

FULL CREAM

Suitable for long term use or as a final stage of graduation to normal feeding

SEPARATED

Almost fat free. Invaluable in cases of fat intolerance

★ Particulars of these and other Cow & Gate preparations for specialised infant feeding will be gladly forwarded on request

FINE CHEMICALS • BIOLOGICALS • PHARMACEUTICALS

research Committee, and with Sir Walter Fletcher had much to do with the shaping of its policy. He served on many boards and committees. He had, however, no real taste for administrative work. First and last he was an investigator, and the strenuous times during which his department was expanding rapidly and the new laboratory was being built (funds for which, with endowment for the Chair, came from the Sir William Dunn bequest) saw also his investigations of biological oxidation mechanisms. This work, notable in itself, inspired a great volume of work not only in this country but throughout the world.

Hopkins was an inspiring teacher, especially of small classes. His policy as head of a research department was peculiarly his own. Many great experimenters focus the whole resources of their department on to the problems in which they are personally interested. Hopkins seldom had more than one or two personal assistants or collaborators; temperamentally he was not an 'organizer' of research in the usual sense of placing himself at the head of a team. On the contrary he encouraged in his department the pursuit of many different lines of work, followed sometimes by different individuals, sometimes by small groups of workers. The result has been a department where discussion and criticism, and the introduction of new techniques and new ideas, have been unusually easy. Visitors came to Hopkins's laboratory from all over the world and never went away without profit to themselves or, indeed, without benefit to Hopkins and his colleagues.

Hopkins had that one hallmark of a great man—real humility of spirit. He was completely devoid of improper pride and pomposity. Though his long life was spent in the laboratory he was always glad he had taken a medical degree. He was a member of the B.M.A. for over forty years and was President of the Section of Physiology and Pharmacology at the Annual Meeting in Cambridge in 1920.

Hopkins married in 1898 Jessie Anne Stevens, and had three children. His son-in-law, Dr E. G. Holmes, has been university lecturer in biochemistry at Cambridge since 1933.

We are indebted to Sir Henry Dale, O.M., F.R.S., for the following appreciation of Sir Gowland Hopkins's scientific work.

Even at a relatively early stage of his career Hopkins, if he looked back on what he had done and discussed what he hoped to achieve, would speak of his real aim in research as being to unravel some part of the intricate complex of linked chemical reactions, catalysed by enzyme systems, which constitute 'intermediary metabolism'—the essential chemistry of life. To such an attempt he regarded all his earlier work as preparatory, and, when opportunity gave him at length an organized department, it was in this direction that he guided the interests and ambitions of his pupils and of the many visitors who came to work under his inspiration. When Hopkins was at the beginning of his work the chemical study of the animal body and its products had become a mere branch of physiology, having some links of practical method with clinical medicine. Chiefly a chemistry of end products, it had almost lost an earlier and short-lived attraction for organic chemists and was not everywhere in great repute with physiologists. He had been conscious of the need to win respect for this 'chemical physiology,' by the achievement of results to which chemists as well as biologists must give attention before the advance towards the real objective could begin. Hopkins lived to see 'organic chemistry' returning, with rapidly growing interest and with immensely greater resources of method and theory, to its original objective of the structure and properties of the relatively stable end-products stored or excreted by animals and plants. He lived also to see the new dynamic chemistry of intermediary metabolism in the foundation and building of which his work and his influence had played such a great part, achieving recognition as the essential 'biochemistry.'

On the way to this ultimate objective Hopkins's work had dealt with a number of apparently separate problems in vital chemistry, so that his career as a research worker seems to fall into periods. In the first he was bringing to the point of publication the work on the pigments of the wings of certain butterflies and their relation to uric acid, begun so early but not published until 1895 when he was already 34 years of age. In his latest years he actually returned to this earliest of all his prob-

lems. To the same early period belongs his work on human purine metabolism, including the introduction of what remained for years the standard method for determining uric acid. Then came the period of protein and amino acid chemistry, beginning with practical methods for crystallizing certain albumins in any required quantity, and culminating in the discovery and isolation of tryptophan. This latter led to the study of the necessity of individual amino acids in a mammalian diet, and thus, apparently, to the recognition of the inadequacy, for growth and maintenance of a diet in which the organic constituents—protein, fat and carbohydrate—had been rigidly purified from traces of unknown factors. This fundamental step towards the recognition of the vitamins, now engaging the attention of such a large proportion of the world's biochemists, was mentioned by Hopkins in a lecture as early as 1907, though circumstances delayed the publication of his detailed experimental evidence till 1912, when the 'accessory food factor' or 'vitamin' conception was already in the air. Hopkins gave the first clear demonstration that it was no defect of appetite or absorption but a fundamental failure of the metabolism to deal with the adequate quantities ingested and absorbed which created the deficiency of the pure diet, and that a relatively minute addition of fresh milk completely repaired the defect. Meanwhile, in 1906, he had published with the late Sir Walter Fletcher the results of the first experiments which he made directly on a problem of intermediary metabolism—the production of lactic acid from carbohydrate in active or injured muscle, and its removal in the intact muscle by oxidation.

It is somewhat remarkable that Hopkins, having been concerned in the same period with two such fundamental researches, from each of which resulted a great new outburst of activity and progress in biochemistry, should have left almost entirely to others the direct exploration of the wide vistas thus opened. His attention, and that of the band of able and devoted pupils who began to gather round him, turned rather in the direction of the enzymatic mechanisms of oxidation in the respiration of the single cell. The isolation of the natural tripeptide glutathione and the complete identification of its structure was, perhaps, Hopkins's culminating individual contribution to this series of investigations. The elegant method which he finally found for the separation of this substance may be compared with that which he had earlier used for the isolation of tryptophan, each affording an example of his apparently instinctive choice of a selective but slightly unconventional reagent for a particular purpose. It may be noted that it was in Hopkins's Institute also that Szent-Gyorgyi later, as a visiting worker, first isolated ascorbic acid, and that it was in the neighbouring Molteno Institute—not under Hopkins's direct inspiration indeed, but not beyond the range of his stimulating influence—that Keilin identified the cytochromes. The study of the reactions of these reversibly oxidized substances and their relations to the activities of different oxidative enzymes has played a large part in the astonishingly rapid development of knowledge of the linked series of reactions involved in cellular oxidations. Another very important contribution to this advance has been made by the succession of Hopkins's pupils who have studied and differentiated the specific oxidative enzymes which can be detected in the cell bodies of living, but not actively multiplying, bacteria of different kinds. The Cambridge School of Biochemistry became, in fact, under Hopkins in his later years a world-famous centre for those investigations on intermediary metabolism towards the initiation and development of which he had been consciously striving throughout his career. He had taken no direct part in the researches, so swiftly extending to the laboratories of all countries, by which individual vitamins were recognized, identified, and produced by artificial synthesis in astonishingly rapid succession, and in a series of which the completion is not even yet in sight. It must have given him a peculiar pleasure, however, to see the specific function of one such pure vitamin after another determined and found to be that of an oxygen carrier or a coenzyme essential to some phase of the complex reactions of intermediary metabolism. For thus the discovery most frequently linked with his name in popular esteem and public recognition as that having the most directly practical application to the betterment of human and animal health, has been brought into an ever closer relation to the deeper problems which had so long held his interest and provided the true goal of his scientific ambition.

SIR ALMROTH WRIGHT

Major General Henry B H Wright CB CMG writes Yesterday I received a copy of the *Journal* dated May 10 and read your obituary notice of my brother, Sir Almroth Wright. It contains some inaccuracies which you may think worth correcting. He died at his residence, Southernwood, Farnham Common Bucks. He gave up his London house in Pembroke Square in 1940. After getting his degrees at Trinity College Dublin with the funds received from the medical travelling prize he proceeded to Germany. On his return from Germany, seeking immediate means of existence, he took a scholarship at the Inns of Court but dropped his legal studies when he passed into the home Civil Service and was appointed to a clerkship at the Admiralty. When his day's work at the Admiralty was done he spent the rest of his day at the Brown Institute, and while still a Civil Servant was awarded the Grocers' Company's research scholarship. With the means thus available he was enabled to resign his appointment in the Civil Service and go to Cambridge University for further study.

He was educated largely on funds provided by the benefactions of others and to some slight extent contributed to the education of others by sending a cheque for £2,000 last year to the funds of T C D.

Sir Thomas Houston writes While appreciating in a high degree the well merited prominence you have given in the *Journal* of May 10 in the obituary and editorial to Sir Almroth Wright the members of the profession here were somewhat disappointed that more emphasis was not laid on his connexions with Ulster. Perhaps you will allow me to add some details to what you have said in this context.

Sir Almroth was born in Richmond Yorkshire, in 1861, shortly before his father, the Rev C H H Wright an Ulsterman was appointed rector of St Mary's Parish, Belfast. During his early days he was educated at the Royal Academical Institution, Belfast and afterwards at Trinity College, Dublin. In his own province—at the Annual Meeting of the British Medical Association in Belfast in 1909—he was president of the Section of Haematology and Vaccine Therapy a section designed to do honour to his work on the blood and on vaccine therapy. In 1912 Belfast gave him the Freedom of the City, and in 1927 the Queen's University conferred on him the honorary degree of Doctor of Laws. He made several communications before the Ulster Medical Society and was an honorary fellow of that Society. The laboratory workers of Ulster owe much to the scientific work of Sir Almroth and to the stimulus of his personality and methods. They always received a warm welcome from him and his staff when they visited St Mary's Hospital. I remember on one occasion I mentioned the success of his typhoid prophylactic inoculations. He replied somewhat as follows: "I would consider it a much greater achievement if I could teach my pupils to make logical deductions and use accurate technique. I would say to them with Pasteur, 'Come away from these polemical discussions come and be taught methods.'" Lord Moran has described Sir Almroth Wright and his distinguished pupil, Sir Alexander Fleming, as "the two doctors who have saved more lives in the field than anyone else in the world."

Dr MARY ARIEL STEWART DEACON formerly of Liverpool died in Carlisle on April 18 at the age of 75. A native of Somerset Dr Deacon was educated at Cheltenham College and at the London School of Medicine for Women. She graduated MB, BS in 1899 and two years later she married Major Thomas Deacon who was then Postmaster General of the Gold Coast. She worked there as medical officer of health at Accra for some years. Then in 1916 she was appointed medical officer to the Royal Army Ordnance Depot at Aintree and continued in this appointment until 1919, when she became assistant medical officer of health for Birkenhead. She took her DPH in 1922 and was in public health work in Birkenhead for seventeen years until her retirement towards the end of 1936. She was at one time president of the Liverpool Women's Medical Association and was appointed MBE in 1918.

D M M writes Dr Deacon who was a strikingly handsome woman had a colourful courageous, and lovable personality. Her career was varied and full of incident and she made friends wherever she went. She will be remembered by countless patients and personal friends for her warm-hearted generosity and the buoyancy of her spirit.

Mr ARTHUR W DOWN founder of Down Bros in 1879 died at his home on April 2 at the age of 95. Mr Down had been a governing director of the company since 1902 and he had entered the industry as early as 1866. He was actively interested in the business up to the last few days of his life, and he will be greatly missed by the friends he made in the course of a long business career which brought him into contact with many doctors.

Medico-Legal

INSTITUTE OF ENDOCRINOLOGY

The Institute of Endocrinology Ltd, of 31, Heath Drive Hampstead, NW3, and Jacques J Harpman, an M D, of La Plata University, were fined £100 with 12 guineas costs at Hampstead Court on Wednesday, May 7, on six summonses relating to a publication of a booklet "Hormone Therapy" advertising preparations for the treatment of epilepsy, infantile paralysis and diabetes.

Mr A C Castle, prosecuting for the Pharmaceutical Society of Great Britain drew attention to the Pharmacy and Medicines Act, 1941. Under the Act, he said, it was an offence for any person, even a doctor, to advertise an article which might be used to treat a number of diseases which might be called very difficult or hopeless diseases. Under section 8 a number of such diseases were listed—in particular it mentioned diabetes, paralysis, and epilepsy. In October, 1946, a Mr John F Armstrong wrote a letter to the Institute asking for particulars of a certain treatment. He received in reply a list of ailments treated by the defendant Company. The three diseases complained of were mentioned. In the same envelope was a booklet entitled "Hormone Therapy." It was apparently a booklet intended to impress on readers the importance of glands and glands, and in particular the pituitary, the thymus, and the pancreas. Regarding those three it mentioned *inter alia* that they were respectively responsible for epilepsy, infantile paralysis, and diabetes. In another part of the pamphlet were the words "glands seldom work correctly. Restore balance by our fresh hormone preparations."

Mr Harpman was interviewed on Feb 11 by an inspector of the Pharmaceutical Society. He said he had qualified as a doctor in South Africa in 1903 and was in practice until 1931. He took his M D at La Plata University. He was 69 years of age. In 1930 he founded the Institute of Endocrinology. The booklet was published in 1935.

Mr Christmas Humphreys, defending said the Institute had done a great deal of good work. There had never previously been any complaint. From 1932 to 1939 the Institute was at Baker Street and it had an enormous practice. Over 200,000 copies of "Hormone Therapy" had been sent out. Then came the Act. The Act discussed "hopeless diseases," and it said no person should claim to treat them. "He may treat them, but may cure them, but he mustn't claim them. He mustn't advertise." The defendants had to plead guilty to claiming to do something which they probably did do. Regarding the sending of the pamphlet, Mr Humphreys continued, there are about two dozen left in existence. Somehow Mr Armstrong was sent the wrong booklet. Since then a new pamphlet had been issued. Mr Humphreys asked for leniency on the grounds of the long standing good record of the Institute and of Mr Harpman the managing director.

Failure of a Restrictive Covenant Correction

Messrs G D CANN and HALLETT Exeter, write You state in the second paragraph of your report (May 17 p 700) of the case in the High Court and Court of Appeal, *Routh and Wilson v Jones* that our client, Dr C G Jones "left the service of the partners and bought a house in Okehampton, intending to set up in practice." This is not the case and the true facts were clearly stated in the evidence before Justice Evershed and in the judgment. Our client had no intention of starting practising in Okehampton when his contract of service was determined by the partners. This house was, in fact, bought before this occurred therefore this report is not correct and we must ask you to amend it.

Medical Notes in Parliament

SCOTTISH HEALTH SERVICE BILL COMMITTEE STAGE

On May 12 the House of Lords went into Committee on the National Health Service (Scotland) Bill. On Clause 3 the Duke of MONTROSE moved to add to the purposes laid down in the Clause the provision of clinics for otological and aural aid services. Lord Rosebery and Lord Cecil of Chelwood supported this amendment.

Lord MORRISON said he agreed with the points that had been put forward. The time was overdue for a campaign throughout the country to give more prominence to this subject. More attention should be given to deafness and the Government had decided to enlist the aid of scientists to make a deaf-aid which could be relied upon and supplied at a reasonable price. Contracts had been placed for an initial supply of 50,000 instruments, of which Scotland would have a fair share. Immediately the Bill was passed preparations would be made to establish throughout Scotland centres where these deaf-aids could be serviced. It was inadvisable to put into the Bill the words which the Duke of Montrose proposed. Subsection 1 of Clause 3 placed on the Secretary of State the duty of providing hospital accommodation, medical, nursing or other services required in hospitals or clinics or services elsewhere. The term hospital included clinics and out-patient departments. Clause 3 also made it clear that the duty of the Secretary of State included the provision of appliances. This provision would be made in hospitals and also in out-patient departments, clinics, and health centres. The Clause did not specify the various kinds of aids and it was impossible to single out deafness for special mention. It would be out of the question to specify all the complaints for which aids were to be provided. There was on the statute book a special Act of Parliament dealing with the arrangements and treatment necessary for cancer—the Cancer Act of 1939—but that Act was now repealed and cancer found no mention in the present Bill because the Government concern was for the treatment of all kinds of ailments. After further discussion the amendment was negatived.

Consultation on Teaching and Research

Lord SELKIRK moved to provide in Clause 3 that the Secretary of State in making available facilities for undergraduate and postgraduate clinical teaching and research should do so after consultation with the universities and the Royal Medical Corporations. He said that in the Bill the hospitals formed a pyramid with the Secretary of State at the top. The medical schools were entirely separated. The only assured contact was on the board of management of individual hospitals or groups of hospitals. In medical education the Secretary of State should look directly to the universities to provide him with advice.

Lord MORRISON said there was nothing in the Bill to debar the universities from a direct approach to the Secretary of State on any difficulty which was not resolved at the regional level. The duty of the Secretary of State under this subsection would not be carried out by himself personally but by the regional hospital boards, acting as his agents. These boards were advised on this aspect of their work by the medical education committee which would be set up under Clause 11. That committee included university nominees. Continuous discussion should not go on with the universities on all questions but merely on questions not resolved in the ordinary way. The machinery of the medical education committee provided in the Bill was put in at the suggestion of the universities. Lord Selkirk withdrew his amendment.

On Clause 5 Lord ROSEBERY moved to provide that special accommodation previously used for patients who undertook to pay should be so set aside subject to accommodation remaining available for other patients. He said that if the amendment was not accepted there would be a mushroom growth of private nursing homes.

Lord MORRISON said that the amendment was similar to one rejected by the House of Commons. He was unable to accept it.

Voluntary Hospital Endowments

On Clause 7 Lord TWEEDSMUIR moved to provide that where property comprised in an endowment was applied to the discharge of liabilities transferred from a voluntary hospital these liabilities must be liabilities which had been incurred for a similar purpose to that for which the endowment had been given by the donor.

Lord MORRISON said this was a matter which would be dealt with by regulations and these could be annulled by either House. The amendment was withdrawn, as was an amendment moved by the Duke of MONTROSE to ensure that the Hospital Endowments Commission would sit in Edinburgh.

The Earl of ELGIN proposed that the powers of the Hospital Endowments Commission should be given for ten years instead of five. This amendment was also negatived.

Regional Boards

On Clause 12 Lord SALTOUN moved to provide that the duty placed upon every regional hospital board to submit a scheme to be exercised by boards of management in the appointment of officers should not apply to a hospital providing facilities for undergraduate and postgraduate clinical teaching. He said the amendment reflected the anxiety of the teaching hospitals that their appointments should remain in their own hands.

Lord MORRISON said the Scottish Bill did not make a sharp distinction between teaching hospitals and non-teaching hospitals. Where a hospital provided facilities for clinical teaching, that was recognized by including on the board of management nominees from the university concerned and from the teaching staff. In the key hospitals which undertook most of the teaching the senior physicians and surgeons were often consultants for areas much wider than those served by the hospitals. The procedure outlined for the appointment of persons to hold clinical posts at a hospital along with teaching posts at a university would not necessarily apply to the most senior appointments—for example, to clinical chairs at universities the holders of which were normally also in clinical charge of hospital wards. Clause 14 was so drafted that these appointments could be excluded from that procedure. The Secretary of State intended to discuss with the universities the arrangements he would make in cases of that kind. The amendment was withdrawn.

On Clause 14, Lord SELKIRK moved that any advisory appointments committee dealing with an appointment involving teaching duties should have equal university and other representation. He said the Bill only gave an assurance that there would be one university representative on the advisory committee.

Lord MORRISON said that the university element on the advisory appointments committee should be in keeping with the relevant importance of the teaching duties as compared with the whole work of the post. He was willing to meet Lord Selkirk to see whether an amendment could be put down later.

Health Centres

On Clause 15, after drafting amendments had been made, Lord SELKIRK moved to provide that a health centre should not be established solely for the provision of general dental services. Lord MORRISON replied that the Secretary of State had assured the dental profession in Scotland that the establishment of a chain of centres providing for dental treatment alone was no part of his plans. In practically every case dental provision would be associated with provision for general medical services. On this assurance the amendment was withdrawn.

On Clause 22 Lord SELKIRK said it seemed that young persons between 16 and 18 were not covered for dental treatment. Lord MORRISON replied that the kind of treatment provided for school-children would not be appropriate for these older boys and girls. The Bill provided a general dental service for the whole population.

Free Choice and Remuneration

Lord SALTOUN moved to vary the wording of Clause 34 so as to provide that regulations might make provision for protecting the right of any person who had complied with the prescribed procedure to choose and change the medical practitioner by whom he was to be attended.

Lord MORRISON said that if the House was anxious for some form of words to be included in the Bill to make it clear that a person could change his doctor a suitable amendment would be devised. The amendment proposed by Lord Saltoun had drafting defects. It was not desirable that a patient should change his doctor frequently.

Lord TWEEDSMUIR moved that regulations should include provision ensuring that the remuneration of general practitioners should be by way of capitation fee subject only to supplementary basic salary as might be prescribed by regulation. He asked whether the basic salary was to be a consolation prize for doctors who did not build up substantial lists of patients or whether it was to be paid to all practitioners at a rate commensurate with present earnings.

Lord MORRISON said it was not proposed by the Government that the salary element should be the main part of the remuneration. The argument in favour of that element was that it would reduce competition for patients and would make it easier for a young doctor to start in practice. It could be increased to attract doctors to under-doctored areas and perhaps also to take account of special experience or qualifications. It was in accord with the proposals put forward by the 1942 Interim Report of the Medical Planning Commission sponsored by the British Medical Association. In replies to the questionnaire issued to all doctors on behalf of the British Medical Association after the publication of the 1944 White Paper only 23% had favoured straightforward capitation fees. Whether basic salary need be a universal element in remuneration had still to be discussed between the Government and the medical profession. Pending those discussions it was not possible to make any further statement on the subject.

Penal Clauses

On Clause 36 Lord SELKIRK moved to add "provided that no offence shall be committed by a medical practitioner or his personal representative who sells his house by *bona fide* public auction". He submitted that verbal assurances from Ministers on this point might carry no weight.

Lord MORRISON said the amendment was unnecessary. In the House of Commons the Lord Advocate had said he could not conceive of any suggestion of prosecution over a genuine auction where the parties had no prior agreement. On the other hand the sale of a doctor's house at an inflated price might readily lend itself to illegal transactions, and the provision in the amendment would tempt people to make a private arrangement and then to cover it by a public auction. The amendment would enable a coach and horses to be driven through the Bill. Lord SELKIRK pointed out that even if the amendment was accepted the sale of a practice would still be illegal. To 'rig' an auction sale would also still remain an offence. Lord MORRISON said the auctioneer would probably not know anything about what happened. The offence might be committed far away from the auction sale. He suggested that Lord Selkirk should consult with legal advisers on whether the words *bona fide* public auction were legally watertight and act accordingly on the report stage. On this understanding Lord Selkirk withdrew his amendment and Clause 36 was agreed to. Lord Selkirk also withdrew a further amendment which sought to provide that no admission or statement made at a hearing before an executive council by a person who was the subject of an inquiry should be admissible as evidence before the tribunal. Lord MORRISON said he would consider this point before the report stage.

Lunacy and Mental Deficiency

On Clause 49 Lord MORRISON said a system was envisaged whereby the medical commissioners and also the medical officers employed by the Board of Control would at the same time hold appointments as officers of the Secretary of State. Reports by these medical men of their visits to particular institutions would be both to the Secretary of State and to the Board. In the great majority of cases these reports would be communicated also to the regional board and to the board of management concerned.

After some discussion of Clause 67 and Clause 77 Lord SELKIRK moved to amend the Second Schedule by substituting the Lord President of the Court of Session for the Secretary of State as chairman of the Hospital Endowments Commission. Lord MORRISON resisted the amendment, which was withdrawn. The Committee Stage concluded.

THIRD READING

On the motion of Lord MORRISON on May 15, drafting amendments were made in Clause 8 to make clear that the purposes to which endowments can be allocated in future by the Commission shall be purposes within the field of the hospital services. Lord MORRISON also accepted an amendment proposed by Lord ELGIN making the term of the Endowments Commission seven years instead of five. This was agreed.

On Clause 11 the House accepted an amendment proposed by Lord MORRISON requiring regional hospital boards to have wider consultations than with universities alone in framing schemes for the constitution of boards of management of hospitals or of groups of hospitals.

On Clause 14 Lord LINLITHGOW moved to provide that in any advisory appointments committee the number of persons nominated by regional hospital boards, boards of management, specialists, and universities should comprise half the total num-

ber of members. Lord MORRISON accepted the amendment, the House agreed to it. Lord MORRISON also accepted an amendment adding research on the development of medical or surgical appliances, including hearing aids, to the purposes set out in Clause 17.

On Clause 34 Lord MORRISON accepted and the House agreed to an amendment which Lord SALTOUN moved. This altered 'conferring a right on any person to choose the medical practitioner' into 'securing a right to any person to choose and change the medical practitioner'. Lord Saltoon hoped that the same privilege would be conferred in the Regulations under the English Bill.

On Clause 43 Lord MORRISON accepted and the House agreed to an amendment providing that practitioners should be informed, as soon as may be, of the substance of any charge or complaint.

Lord MORRISON then moved the Third Reading of the Bill and thanked the House for the reception given to it. He said the amendments made improved the Bill. On behalf of Mr Westwood he gave an assurance that a hospital would not be discontinued until other provision as adequate had been made for the people served by it. He explained that regional hospital boards and boards of management had powers to provide refresher courses for their own employees. It was open to the three executive authorities, the regional hospital board, the local health authority, and the executive council, to take initiative in proposing arrangements for co-ordinating services.

Lord MORRISON mentioned that Mr Westwood had recently recommended from his Medical Advisory Committee that there should be in Scotland a comprehensive laboratory covering pathology and biochemistry, as well as bacteriology. Mr Westwood accepted that recommendation and intended to act on it. Clause 18, subsection 2, enabled all the Secretary of State's functions in relation to laboratories to be discharged by a comprehensive service associated with the hospital service. Mr Westwood did not think that at the inauguration of the new service people employed in the present health services would find themselves without jobs and without compensation. In the new service there would be need of those with knowledge and experience of the existing services. The aim of the Bill was that the Board of Control should continue to be an independent body. Members of the Board would hold their appointments from the Crown. Not all the members of the Board would be officers also of the Secretary of State. Wholly independent persons otherwise unconnected with Government Departments would continue to hold part-time appointments as members of the Board.

The Bill was read a third time and returned to the Committee with amendments.

The amendments made by the House of Lords to the National Health Service (Scotland) Bill were considered by the House of Commons on Tuesday, May 20.

UNIVERSITY EDUCATION

Lord LINDSAY of Birker in the House of Lords on May 15 opened the debate on university education. He said Parliament was committed to a great increase in the university population of England. He urged the Government either to ask the University Grants Committee to appoint a subcommittee to investigate the results of an increase in the number of undergraduates or else to appoint a departmental committee of which the University Grants Committee would be representative. Great changes were imminent in university education in Great Britain as a result of the Butler Education Act. The Butler Act removed the reproach that in England secondary education was confined to a small proportion of the population.

In 1934, one in every 473 of the population of Scotland went to a university, in the United States one in every 125, in England one in every 1,013, and in Wales one in every 741. These proportions were due to historical and social factors and ought to cease. The Barlow Report had recommended that the output of trained scientific graduates in this country must at least be doubled. Then there was the additional demand for professional men, especially for doctors. To have a properly equipped health service the country must have a far greater number of trained doctors, who ought to be university trained and understand what research meant. That involved a great increase in the number of medical undergraduates. Science developed so rapidly that graduates who went in for medicine found their knowledge rapidly becoming out of date. It was well worth while bringing people back to the universities for special courses. Was the university population to be preserved by asking existing institutions to double their number and to preserve their character? The University Grants Committee had asked universities and university colleges how much it

ould add to their numbers supposing they were given money or staff and buildings. Their answers added up to 80% of the 100% required. The State would provide the money but building was held up by want of licences and universities were troubled about the question of staff. There were proposals for new institutions from Stoke-on-Trent and from York, Carlisle, Brighton, and other places. No authoritative body seriously considered these proposals. Should these new institutions be of the existing type? In existing university colleges students took their degrees from the University of London and he was not sure that the obligation to work for the degrees of that University did not fetter the initiative of the smaller institutions.

University Grants Committee

Lord Jowitt, the Lord Chancellor, said he had recently been in touch with the University Grants Committee and knew its outlook. It was a most useful piece of machinery. He conceded that the university population was too small and must be increased as soon as possible. The Barlow Report had recommended that it should be doubled in ten years and it was likely that in the next ten years it would have to be doubled again. In 1938 the country had a university population of something like 50,000. To-day it was something like 66,000, and he hoped that in 1951 it would have reached 88,000. The Chancellor of the Exchequer was prepared to find the money, but the difficulties were in finding teachers of sufficiently high ability and in the building problem. The new terms of reference of the University Grants Committee were: 'To assist, in consultation with the universities and other bodies concerned with the preparation and execution of such plans for the development of the universities as may from time to time be required in order to ensure that they are fully adequate to national needs.' These were wide terms of reference and the Lord Chancellor did not think it would be wise to appoint another committee.

Lord CERRWELL said the proper function of a university was incompatible with central supervision and control of what was taught and taught. The universities had become very dependent on Government financial support and it was necessary to safeguard their independence. He denied the statement in the Barlow Report that Oxford and Cambridge were unwilling to expand.

Lord BEVERIDGE said the Chancellor of the Exchequer had provided enough money to enable £40,000,000 worth of building to be done at the universities. The universities had gone to the licensing authorities and found that they could have only 50% or even less of what they wanted. There was a real danger that universities were compelled to apply for licences to only regional authorities. Natural scientists had the money they needed for research but social scientists did not.

Lord SIMON of Wythenshawe said Oxford and Cambridge, London, Edinburgh and Glasgow were expanding only moderately. The burden was going to fall on the regional universities and colleges.

Lord LINDSAY of Birker withdrew his motion.

Radio-active Substances Bill

Lord ADDISON speaking on May 12 on the business of the House of Lords said consultations were still going on concerning the Radio active Substances Bill. The Government wanted to be able to proceed with this Bill as an agreed measure and was anxious for a little more time. He therefore proposed to postpone the Second Reading which had been set down for the following day. Lord WOOLTON for the Opposition, concurred.

RIGHTS OF THE SUBJECT BILL

The Preservation of the Rights of the Subject Bill came before the House of Lords on May 15 when Lord READING moved its second reading. He said it was an attempt to safeguard or to restore certain rights of the subject and it had been prepared by the Liberal Party. The Party asked that it should be given a fair chance to find its way to the Statute Book. Its earlier drafts were directed to remedying the growing usurpation by the Executive of the powers of Parliament and the increasing exclusion of the Courts of Law from their supreme function of protecting the individual citizen against excessive encroachments on his right and against abuses of authority. These tendencies had been nurtured by the conditions of two long wars but there was no reason why they should be perpetuated without being curtailed by reasonable restraints. Lord SIMON said there was no question of objecting to the process by which Parliament authorized delegation to the proper authorities under proper conditions. The danger was

that under the authority so delegated the country might have what were really extra Acts of Parliament. Regulations were sometimes made which were obnoxious and contrary to the public interest. Proper safeguards were required in regard to these things. There was a dangerous tendency to assume in some quarters that a majority in the House of Commons was there simply to register decisions which had been reached by the Government of the day. He welcomed the Bill.

Suppression of Periodicals

Lord LAYTON drew attention to Clause 7 which dealt with the freedom of the Press and the suppression of newspapers. He said the Clause seemed necessary to ensure that freedom of publication was not subject to departmental interference. That issue arose last February. The periodical Press was suddenly brought into contact with a new set of officials. These officials who had never before been in contact with the Press dealt with this issue, although there existed in the Government a department whose officials had been in constant touch with the Press for seven years. The action taken showed the departmental exercise of discrimination between publications. Periodicals were stopped and newspapers were allowed to continue. Subsequently a distinction was drawn between essential newspapers and unessential newspapers. To prevent competition between the periodicals which were suspended and those which were not, the ban was made to include the production of periodicals even though they consumed no fuel at all. This was a ludicrous situation. To stop all devices which enabled the Press to appear was an ominous act. It was subsequently said that the restriction on the Press was by way of an instruction which had no legal validity but that the statutory regulation could have been issued. The grounds on which a statutory regulation could be issued were contained in the Supplies and Services (Transitional Powers) Act. He doubted whether any regulation under that Act could have been issued to impose a restriction on the Press. But if the power existed the case was made out for Clause 7 of the Bill before the House. He noted that periodicals were consuming 29.3% of their pre-war consumption of paper but the Stationery Office and Government Departments were consuming 177%.

The Willesden Case

Lord SAMUEL, speaking on Clause 12, recalled the case at Willesden where the borough council had issued notices of dismissal to medical officers and nurses for the reason that they were not members of particular associations of their profession. There had been an instant public outcry and the borough council withdrew from the position it had taken up. If the council had refused to withdraw and if a number of other local authorities had taken similar action public opinion would not have tolerated this and it would have been suppressed by legislation. When so much pressure was put on the individual that he was compelled against his will to do certain things, economic force was being applied to such a degree that essential human liberty was infringed.

The LORD CHANCELLOR said it was a thoroughly bad principle to dress up a manifesto as a Bill. That was what was being done. The Bill was ill-considered, ill-digested, and ill-drafted. To prevent the Parliamentary machine from breaking down Parliament must have an adequate arrangement for delegating legislation. On Clause 7, which dealt with the suppression of publications, he noted that the Defence Regulations contained no express power now in force to suspend a paper as such but there was power under Regulation 55 to prohibit the production of any article for the purpose of securing a sufficiency of supplies essential to the well-being of the community. If there was an inadequate amount of paper the Government might have to decide for what purpose it was to be used. The Government must continue to have that power under Regulation 55. The particular periodicals which were recently suspended were not dealt with under Regulation 55. The order was made as the result of an understanding reached with the newsprint supply companies and the Periodical Proprietors' Association. The arrangements were made as a result of an understanding reached with those bodies.

Lord LAYTON intervened to say that the newsprint supply companies took no responsibility whatever for suppression. A power of suppression which discriminated between newspapers was not really necessary for regulation purposes. If the Government had approached the Press it would have found a way of economizing fuel without suppressing any specific group of newspapers.

The LORD CHANCELLOR then adversely criticized other Clauses of the Bill. On a division the Bill was read a second time by 37 to 19.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended May 3

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland

Figures of Births and Deaths and of Deaths recorded under each infectious disease are for (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland

A dash — denotes no cases a blank space denotes disease not notifiable or no return available

Disease	1947					1946 (Corresponding Week)				
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)

† Includes primary form for England and Wales London (administrative county) and Northern Ireland

‡ Includes puerperal fever for England and Wales and Eire

EPIDEMIOLOGICAL NOTES

Food poisoning in Coventry

On Wednesday, May 14, 12 cases of suspected food poison were notified to the Coventry public health department. It was quickly confirmed that an article of diet common to sufferers was from a consignment of "liver sausage retail fairly widely throughout the city on Tuesday, May 13. Free supplies of this commodity are delivered by the manufacturer to the Coventry area daily. In all cases symptoms were apparent within a few hours of eating the sausage. The illness was characterized by acute abdominal pains, vomiting, profuse watery diarrhoea, and in several cases there were signs of severe shock and collapse. The temperature was of moderate degree, being about 100 F (37.8°C) in cases admitted to hospital.

During the day all retailers selling the liver sausage were visited, and several samples were forwarded to the local laboratory for analysis. The manufacturers are withholding distribution of the preparation until further notice. All cases notified were followed up, and by the end of the day some 60 cases in twenty-five households had been discovered. On Thursday, May 15, other cases were notified, and investigation brought to light a further 15 cases in seven households. Reports from the laboratory now showed all samples of the liver sausage to be heavily contaminated with *Staphylococcus aureus*.

There were no fresh notifications on Friday, May 16, but retailers were visited by inspectors, and following a careful inquiry an additional 27 cases were traced in fourteen households. On May 17 eight delayed notifications were received.

During the four days May 14-17, inclusive, 111 cases were traced, and all had eaten "liver sausage" from the Tuesday consignment. Five patients were removed to the municipal hospital in a state of severe collapse, although it is certain that many of those treated at home by general practitioners were also very severely affected. Fortunately, at the time of going to press no deaths have been reported.

Smallpox

Two further cases of smallpox have appeared in connection with the outbreak at Bilston. An unvaccinated woman aged 35 was taken ill on May 9 and developed a scarlatiniform rash on May 12, on May 16 it was recognized that she was suffering from haemorrhagic smallpox and she was removed to hospital where she died the same day. The source of her infection is at present unknown. At Birmingham a medical student who visited the Bilston smallpox hospital on April 24 and was unsuccessfully revaccinated on the same day has developed a mild attack of smallpox with an atypical eruption.

A case of smallpox was removed to hospital from a Salvation Army hostel in Bermondsey, London, on May 16. This was an unvaccinated man, aged 22, who had come to London from a lodging house at Barnsley on May 6. His illness began on May 12 and the rash appeared on May 16.

Inquiries at Barnsley revealed that three residents of the lodging-house connected with the Bermondsey case were suffering from smallpox. In two men, aged 72 and 76, the onset appears to have been on May 12, and in a woman, aged 45, on May 15. All three were removed to a smallpox hospital on May 16.

Discussion of Table

In England and Wales there were increases in the incidence of measles 480 and dysentery 61 and a decrease in the notifications of acute pneumonia 131.

There were no large fluctuations in the local returns of scarlet fever and whooping cough. The only change in the incidence of diphtheria was an increase of 12 in Yorkshire West Riding. The increase in cases of measles was due to a sharp rise in a few counties, notably Yorkshire West Riding 243, Glamorgan 206, Derbyshire 135, and Lancashire 81.

The increase in the notifications of dysentery was confined to Lancashire, where the cases increased from 19 to 76. The principal centres of infection in this county were Prestwich M.B. 17, St Helens C.B. 18 and Liverpool C.B. 15.

In Scotland infectious diseases were less prevalent, and there were falls in the notifications of whooping cough 67, acute primary pneumonia 65, scarlet fever 25, and diphtheria 1. There were 4 more cases of cerebrospinal fever in the west area.

In Eire the only changes of note were decreases in the notifications of whooping-cough 19 and diphtheria 13.

In Northern Ireland a fall was recorded in the notifications of measles 16, scarlet fever 15, whooping-cough 7, diphtheria 7.

Week Ending May 10

The notifications of infectious diseases in England and Wales during the week included scarlet fever 1,002, whooping-cough 2,222, diphtheria 194, measles 10,134, acute pneumonia 561, cerebrospinal fever 74, dysentery 110, acute poliomyelitis 12, paratyphoid 3, typhoid 6, smallpox 2

Medical News

The Council of the Society of Medical Officers of Health last week gave a lunch in honour of Dr George F Buchan to mark the occasion of his retirement as Medical Officer of Health for Willesden and the conferment on him of the Honorary Fellowship of the Society. Sir Allen Daley presided. Dr Buchan was previously President and Treasurer of the Society and has been re-elected Chairman of its Council. At the lunch, Sir Allen Daley, Sir Wilson Jameson, Dr James Fenton, Sir George Elhston, and Dr Frank Gray spoke in warm terms of Dr Buchan as a man who has left his mark on public health.

Dr H V Dicks, Nuffield Professor of Psychiatry at the University of Leeds, will give a talk in the Third Programme on May 26 at 6 p.m. on "German Character Structure".

The last meeting this session of the Scottish Group of the Association of Industrial Medical Officers will be held at the Institute of Hygiene, University of Glasgow, on Wednesday May 28 at 2.45 p.m., when short papers will be read by Dr D M Watson on "Industrial Sickness Absence," and by Dr Edward Collier on "Prevention and Control of Industrial Oil Dermatitis." A business meeting will follow.

Sir Stanford Cade will deliver an address on "Recent Advances in the Treatment of Cancer" before the Medico-Chirurgical Society of Anderson's College and St Mungo's College in the Lister Theatre, Glasgow Royal Infirmary, on Friday, May 30, at 7.30 p.m.

A clinicopathological demonstration of chronic mastitis will be given in the Meyerstein Lecture Theatre of Westminster Hospital School of Medicine (Horseferry Road, S.W.), on Monday, June 2, at 5 p.m.

The eleventh International Congress of Military Medicine and Pharmacy will be held at Basle on June 2-7. As a result of the successful inter-allied meeting on war surgery held in Paris during the first world war, the first International Congress of Military Medicine met in Brussels in 1921 and founded an international committee. Between then and the second world war this organization held congresses in various parts of the world to study and discuss military medicine, but, whereas between the wars it was relatively easy to communicate across national boundaries, the situation is now much more difficult. In the recent war the countries of Western Europe became intellectually isolated from the combatants, and in addition the world-wide nature of the war raised problems that have not been adequately discussed. This conference will therefore afford an excellent opportunity for the exchange of views on military medicine, and the Secretary-General suggests that a department of medical education should be instituted within the committee, which would co-ordinate and publish together scattered documents on military medicine. His address is Le Général Médecin J Voncken, Comité International de Médecine et de Pharmacie Militaire, Liège, Belgium.

The first post-war dinner of the Edinburgh University Club of London will be held at the Café Royal on Thursday, June 5, when the Principal Sir John Fraser, Bt, FRCS(Ed.), will be the guest of honour. The Rt Hon Sir John Anderson, P.C., M.P., will preside. The annual general meeting will precede the dinner. Any member who has not received his official notice by May 29 is requested to communicate with the honorary secretary at 12, Wimpole Street, London W.1.

The third Joint Conference of Advisory Councils on Industrial Health was held at Burton-on-Trent on May 22 when the three original bodies, Leeds, Derby, and Burton-on-Trent, were represented. Reports of the year's work by the various councils were given and a discuss on took place. At a later session Dr H E Magre (Ministry of Food) opened a discussion on "Nutrition in Industry".

Dr Donald Paterson, FRCP, who has for some years practised as a paediatrician in London, returned to his home in Canada on May 17. Letters to him should be addressed temporarily c/o Royal Bank, Vancouver, B.C. Dr Paterson has been made President of the British Paediatric Association for 1947-8.

Dr Franklin Kidd, FRS, superintendent of the Low Temperature Research Station, has been appointed Director of Food Investigation Department of Scientific and Industrial Research from April 1, in succession to Dr C S Hanes, FRS.

Any Questions ?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Pethidine

Q—What are the objections to the continued use of pethidine so long as clinical improvement is maintained? Does addiction necessarily follow and what are its signs, symptoms, consequences, and treatment?

A—There are no objections to the continued use of pethidine in any given case, apart from the risk of addiction. While this risk exists, the published evidence makes it clear that it is much less than with morphine. Himmelsbach (J Pharmacol 1942, 75, 64) showed that pethidine when given *ad lib* for ten weeks to previous drug addicts caused a similar dependence to that produced by morphine. On the other hand, Batterman (Arch Intern Med 1945, 71, 345) gave effective clinical doses of pethidine for prolonged periods for relief of pain without encountering any symptoms when the drug was stopped. Excessive doses (100 mg eight times a day) caused nervousness, irritability, dryness of the mouth, and sleepiness. The symptoms which may occur on withdrawal of the drug are yawning, lacrimation, rhinorrhoea, perspiration, gooseflesh, and dilated pupils. Tolerance does not commonly occur, thus 115 patients receiving 42 to 492 doses of pethidine in 4 to 28 weeks developed no appreciable tolerance to its analgesic action, and it was not necessary to increase the dose as time passed.

Nocturnal Enuresis

Q—What can be done for two little girls aged 7 and 3 who suffer from enuresis?

A—There are so many causes of bed-wetting—from mental deficiency and physiological causes like acid urine to the boy whose sister out of jealousy used to empty the chamber in the bed after he was asleep—that no one remedy can be suggested. The most common cause is latent anxiety, which was so prevalent among evacuated children during the war. It is commonly due to a desire to return to the protection and security of infantile life. As the child gets bigger and more confident it outgrows the anxiety, and the enuresis passes. In other cases it is a form of sensuous gratification, especially in girls because of the proximity of the clitoris. In this type the enuresis ceases when normal sex feelings develop at puberty, but sometimes it may act as a check to such development. Very often it is used as an expression of resentment and of defiance. Other children wet themselves because they like the attention which accompanies it.

What is right treatment for one case is often wrong for another, and for this reason an accurate diagnosis should be made, if necessary the help of a capable child psychiatrist should be secured. Perpetual lifting, worry, and fussing over the child are likely to perpetuate the condition, therefore, in the absence of a correct diagnosis, it is best to let well alone. In some children's homes it was found that putting up a "star" above the bed as a reward was effective, but it may discourage a child who in spite of the desire for a "star," cannot help wetting the bed.

Chronic Nasal Blush

Q—What are the cause and the treatment of a deep red coloration at the end of the nose during a meal or in a hot room in a woman of 39 who is a non-smoker and is abstemious but who leads an active and worrying life in business? She makes no complaint of indigestion.

A—The vasomotor phenomena described in the question are common but ill understood. The red nose of the music-hall comedian bears witness to the popular view of its aetiology. In a related disorder—acne rosacea—evidence has been published suggesting the importance of psychological factors and the affection has been regarded as analogous to a chronic blush. In the present instance there is clearly a reflex vasodilatation,

competent stimuli being eating and a raised external temperature. There is no way of abolishing a specific reflex, although sedation will damp down such activity. No method of controlling the effector end of the reflex is known, thus the only rational therapeutic approach is by removing the stimulus. Inquiry should be made to define the stimulus more precisely; it is important to know whether specific foods are responsible. When the adequate stimuli are defined more exactly the patient will have to order her life so as to avoid them as much as possible.

Angina Pectoris

Q—A man of 54 has sudden attacks of acute pain in the region of the fourth rib just left of the sternum accompanied by transient aching down the left arm followed by numbness. Blood pressure 140/85 mm pulse unchanged, no cyanosis or pallor. In the acute stage he has a choking feeling and the mouth is dry. Heart and chest clear on x-ray examination, electrocardiogram normal, Wassermann negative. He has some hypoglycaemia but prolonged treatment with glucose has been ineffective.

A—This history is suggestive of angina pectoris, and knowledge of the factors which precipitate attacks would be of diagnostic value. If they are occasioned by effort, it would be hard to avoid the conclusion that they are anginal. It is stated that the electrocardiogram is "normal", such a finding does not exclude angina pectoris but when chest leads are used it is rare to be unable to demonstrate some abnormality. Pain of this type has been described with diaphragmatic hernia, especially of the para-oesophageal variety. It would be worth asking a radiologist to carry out an opaque meal examination with this possibility in view.

Smoking Habit Cures

Q—Are the so-called smoking habit cures reasonably effective? What is their nature and have they any ill effects?

A—Smoking habit cures are of all kinds and depend very largely for their success on the desire of the subject to be cured. The principal point in the treatment is to keep the thoughts of the patient off the topic of tobacco and to supply the accustomed stimulus to the mouth in some other manner, as by chewing ginger or gentian. Cures of this kind are at least harmless.

Malaria Recurrences

Q—For how many years may a patient who has left the Tropics continue to have recurrences of malaria?

A—Falciparum infections are usually short lived, but attacks of the other types of malaria may recur for a year or two after the primary infection. Quartan infections are the most persistent, and in rare cases recurrences have occurred many years after the initial infection. A fact to be remembered in practice is that many patients who have had malaria may describe symptoms suggesting an attack or they may attribute any malaise to malaria for years after the initial infection, but in the great majority of these cases no parasites are demonstrated. In any case, malaria is now so readily controllable that, properly handled, relapses in this country should prove no real practical disability.

Neonatal Respiration

Q—Does gaseous exchange take place in a newborn infant while pulsation continues in the cord? If so is it advisable to cut the cord in an asphyxiated infant while pulsation is present?

A—Once the foetus is born the uterus retracts so strongly that the circulation in the maternal sinuses is impeded, and it is unlikely that the transfer of much oxygen takes place through the placenta even when the cord is still pulsating. It is this which accounts for the sudden development or increase in anaemia, which is the most important stimulus for the onset of respiration, and the very occurrence of asphyxia livida is evidence of cessation of placental function. The value of any delay in cutting the cord is that it enables the child to recover as much as possible of the very considerable proportion of its blood which ordinarily circulates in the vessels of the cord and placenta.

Halitosis

Q—A healthy girl suffers from halitosis for which ear, nose and throat examination reveals no cause, the condition is improved by alkalis. Will she grow out of it? Is there an objection to taking alkalis indefinitely or is there some other efficacious treatment?

A—Foetor oris is commonly due to dental disease, no mention is made of the state of the teeth and gums. An adequate dental examination is important. The symptom is almost always due to some disorder of the upper respiratory or alimentary tract, its origin is gastric only when there is gross disease of the stomach. Further search for the cause is advisable in this case. Prolonged dosage with alkalis is not without danger, large doses may lead to renal damage.

Facial Hair in a Girl

Q—A girl aged 16 is developing a fairly marked growth of hair on her upper lip. Her periods started late and are now scanty and irregular. She is somewhat backward at school. Would hormone treatment have any effect?

A—The girl is probably suffering from either overactivity of the adrenal cortex, a masculinizing tumour of the ovary or pituitary basophilism. The most likely condition is bilateral adrenal cortical hyperplasia, and there may well be a constitutional causal factor as manifested by facial hirsuties in other near relatives. A very full investigation, including hormone assays (for example an estimation of the excretion of 17 keto steroids) and possibly pelvic examination under anaesthesia, is indicated before any decision is made as to treatment. No matter what its cause may be, the treatment of facial hirsuties by hormones is usually unsatisfactory. If, however, an androgenic tumour is found and removed, the growth of hair usually ceases.

Calcareous Deposits in Eyelids

Q—A patient aged 45 with corrected hypermetropia suffers from gravel (stones) in the upper eyelids. The lids have been scraped with either a needle or bluestone. Penicillin drops have not helped. Can you recommend any local drops or ointment or any special diet to prevent the formation of the stones or to assist in dissolving them?

A—The cause of deposition of calcareous nodules in the tarsal conjunctiva is unknown. There is no reason to believe that it is connected with refractive errors or with a chronic infective state of the conjunctiva. Neither glasses nor penicillin would, therefore, be of value. Removal of these calcareous nodules by digging them out with the point of a Graefe knife is the only known treatment of any value. Unfortunately recurrences are common, and there is nothing one can do except further surgical removal.

Menopausal Adiposity

Q—A woman without other menopausal symptoms has suddenly developed increasing adiposity. Dietary treatment and exercise are without effect. What would you suggest?

A—Adiposity may have its onset at the climacteric, and in the view of the writer it is associated with climacteric hyperplasia of the anterior pituitary and adrenal cortex in people of certain endocrine constitution. There is no specific hormone therapy. Modification of the adiposity depends upon thyroid, and mercurial diuretics.

DENTAL CONDITION OF FIVE-YEAR-OLD CHILDREN IN INSTITUTIONS AND PRIVATE SCHOOLS COMPARED WITH L.C.C. SCHOOLS

BY

HELEN COUMOULOS, Ph D Camb, D D S Athens

AND

MAY MELLANBY

with the assistance of Irene Allen

From time to time in the literature the dental condition of various races, social classes, types of school, and so on is compared. If the differences observed are so big that they are self-evident—as, for instance, the difference in caries incidence between children in Great Britain and children of certain native races living in their natural habitat—the criteria used in assessing these differences are for many purposes perhaps not of great importance. Should the discrepancies be less outstanding, however, it is essential that the same standards and the same age groups should be used in the examination of each race, class, or school if true comparisons are to be made. This is especially necessary if the effect of specific procedures or dietary factors is being put to the test.

It is we believe, unfortunate that the majority of workers when investigating the dental condition of groups of people, concentrate only on caries incidence and sometimes its extent, ignoring the structure of the teeth, or, if they consider it at all, recognizing only one type of defect—that to which we and our colleagues refer as gross or G hypoplasia. Thus valuable data are lost.

It is often stated that children brought up in institutions have less caries than their contemporaries living in their own homes. As we had had long experience in examining and charting the deciduous teeth of children attending public elementary schools, using the same standards throughout (Mellanby and Coumoulos, 1944, 1946, Coumoulos 1946) and had accumulated much information on the subject, we determined in 1945 to see for ourselves how the dental condition of institutional children compared with that of some other sections of the community of the same age groups. During the same period we also made a study of children living at home and attending private schools and in this paper we shall compare in some detail the findings in the 5-year-old children of these two groups with each other and with data obtained from children of similar age residing usually in their own homes and attending L.C.C. schools in the same year. Details of this last group have already been published (Mellanby and Coumoulos 1946).

In the present study we use the term 'institutions' to cover communal homes for children deprived of a normal home life for one reason or another such as destitution, illegitimacy or the death of one or both parents. Some of the institutions visited in the course of the investigation were run by municipal or education authorities, others by religious or charitable organizations. The selection was made as representative as possible and for this we have to thank Dr H. E. Magee of the Ministry of Health.

The majority of the children in the institutions were from poor or unsatisfactory homes. The private schools ranged from the small "select" type to larger ones attached to senior schools, and, so far as could be judged from information supplied, most of the children attending them came from well-to-do families. Many of the children attending the L.C.C. schools were of poor parentage, although some were of a higher social grade. The method of examination and the criteria used in the assessment of dental structure, caries, and other conditions have been described previously (Mellanby and Coumoulos, 1946, and earlier publications by M. M. and colleagues).

Results

A comparison of the findings in the three surveys under review is given in Tables I to VIII. Table I indicates that

TABLE I—Percentages of Teeth Present at Time of Inspection

Type of Tooth	Institutions	Private Schools	L.C.C. Schools
Upper			
Centrals	94.0	93.5	92.6
Laterals	97.8	99.2	98.3
Canines	99.8	100.0	99.6
1st molars	99.5	98.2	95.0
2nd molars	99.8	99.5	97.5
Lower			
Centrals	85.7	76.0	79.4
Laterals	98.5	97.4	98.0
Canines	100.0	99.9	99.9
1st molars	98.6	95.4	92.4
2nd molars	99.2	93.4	91.7
All types	97.3	95.8	94.4

comparatively few teeth were missing, either shed or extracted, from any of the groups of children. Our chief concern was with the structure of the deciduous teeth and their caries incidence and extent rather than with the state of the teeth per child, but before considering these points in detail mention may be made of the percentages of children found to be free or almost free from caries (see Mellanby and Coumoulos, 1946). Table II shows that the

TABLE II—Percentages of Children Caries free or Almost Caries free

Place of Investigation	No. of Children Examined	Caries free	Almost Caries free	Total
Institutions	325	57.2	8.9	66.1
Private schools	371	50.4	4.3	54.7
L.C.C. schools	691	24.2	3.9	28.1

institutions had a larger percentage (66.1) in this category than the private schools (54.7), which in turn showed a great advance on the L.C.C. schools (28.1).

In dealing with the individual types of teeth and with the teeth as a whole, the surface structure will be mentioned first, as we consider this to be very important in relation to their resistance to caries

Surface Structure of the Teeth

As is seen from Table III, the children attending private schools had many more teeth graded as Hy₀—that is to say of good structure (54%)—than either those attending the LCC schools (38%) or those living in institutions (32.3%). In other words, structure was by far the best in the private schools and was worst in the institutions. As would be expected, when each individual type of tooth was considered, the children at private schools

the institutional children, 10.3% of the first and 10.5% of the second molars being affected, whereas the figures for private and LCC schools ranged from 1.1 to 2.6% for the same types of teeth

The average hypoplasia figure (AHF), which relates only to M-hypoplasia (see McIlanby and Coumoulos, 1946) and gives a rough computation of the extent of this imperfection, was lowest for all types of teeth together in the private schools, but was approximately the same for the other two groups—that is, 0.6 in the private schools compared with 0.92 in the institutions and 0.91 in the LCC schools. Again, the AHF for each type of tooth was lower for the private schools group than for either of the others, which varied slightly from tooth to tooth. In all

TABLE III—Comparison of Tooth Structure in Institutions Private Schools and LCC Schools

* AHF (average hypoplasia figure) = $\frac{\text{Total hypoplasia figure}}{\text{Total no. of teeth examined for structure (excluding those with G hypoplasia or unclassified hypoplasia)}}$

were consistently at the head of the scale, and those attending LCC schools were in most cases better than those residing in institutions

The proportion of teeth showing some degree of M-hypoplasia was least in the private schools group (44.3%) and much higher in the institutions (62.1%) and LCC schools (59.1%). Comparatively few in any group showed severe M-hypoplasia (M-Hy₃), taking all types together, the private schools had 1.2%, the institutions 1.7%, and the LCC schools 3.5%

Gross hypoplasia (G-Hy) was negligible compared with M-hypoplasia. The institutions had 4.8% showing this condition compared with 6.2% with M-hypoplasia, the LCC schools 2.3% compared with 5.9%, and the private schools only 1.3% compared with 4.2%. These figures for gross hypoplasia correspond roughly to the figures usually given in the textbooks for all generally recognized hypoplasias (Pitts 1921, Ainsworth and Young, 1925). Taking individual types of teeth the highest percentages with gross hypoplasia were found in the lower molars of

groups the lower incisors had the smallest AHF and second molars the greatest—a fact which has been observed in all investigations where the same standards have been used in the assessment of structural defects in deciduous teeth

Incidence and Extent of Caries

When we turn to the subject of caries quite a different picture is presented. As is shown in Table IV, the percentage of carious teeth of all types together was some what lower in the institutions than in the private schools, in spite of the fact that the structure of the teeth was so much worse, and much lower than in the LCC schools, the respective figures being 10.5%, 14.2%, and 26.5%. In general, the same relation was evident between the three groups when each type of tooth was considered separately. As is usually found, in all three groups the lower incisors were rarely carious, only 2.1% or less in any group coming into this category, and the highest incidence occurred in the second molars, the lower teeth of this type being worse

than the upper. In the institutions 26.3%, in the private schools 34.9%, and in the LCC schools 58.8% of the lower second molars were carious.

Just as comparatively few teeth in any group were severely affected by M-hypoplasia, so few showed severe caries, only 8.3% or less of the teeth in any group being in this category (C_3). The lowest incidence of this grade was found among the institutional children—that is to say, in those with teeth of the worst structure—and the greatest incidence among those attending the LCC schools (It should be noted that this category, as in previous investigations, includes the relatively few missing canines and molars, which are assumed at the age of 5 years to have been extracted for caries—see figures in brackets in Table IV.)

In each group of children and for each type of tooth in the present survey the percentage of carious teeth increased with the severity of the M-hypoplasia, but there were some very marked differences between the groups especially in relation to the worst grades of structure ($M-Hv_2$ and $M-Hy_3$). It is seen in Table V, for instance, that 56.8% of the molars graded as $M-Hy_2$ in the private schools and 66.5% in the LCC schools were carious, whereas the corresponding figure for the institutions was only 29.8%. Similarly, for the molars graded as $M-Hy_3$ the percentages of carious teeth were 89.6 for the private schools, 92.3 for the LCC schools, and only 58.2 for the institutions. The same trend is apparent when other grades of structure and other types of teeth are considered.

TABLE IV—Caries Incidence and Extent in Institutions Private Schools and LCC Schools

* Caries-affected figures include missing canines and molars which are assumed to have been extracted for caries.

Figures in brackets show these teeth as percentages.

† ACF (average caries figure) = $\frac{\text{Total caries figure}}{\text{Total no. of teeth (including extractions)}}$

The average caries figure (ACF) which indicates the extent of caries was lowest for all types of teeth together in the institutional group (0.19) and highest in the LCC schools group (0.55) with the figure for private schools (0.28) in an intermediate position but nearer to the institutional than the LCC schools figure.

Thus it is seen that whereas the structure of the teeth was definitely the best in the children attending private schools and worst in those living in institutions there was less caries in the teeth of the institutional children than in the private schools group. The LCC group had most caries much more than either of the other two, in spite of the fact that the structure of their teeth was better than that of the institutional children although not nearly as good as that of the private school group.

Relationship between Structure of Teeth and their Susceptibility to Caries

As would be expected from previous investigations (McLanby 1923, 1934; McLanby and Coumoulos 1946)

The similarities and discrepancies between the findings for the three groups of children are perhaps more clearly seen if they are set out as shown below. (The figures given here are for all types of teeth together and not, as in Table V, for individual types.)

No caries was found in

Inst	Private Schools	LCC Schools
99.7%	98.7%	98.1%
95.2%	84.4%	83.2%
72.2%	48.6%	40.9%
45.8%	13.8%	15.3%

Severe caries was found in

Inst	Private Schools	LCC Schools
0.0%	0.0%	0.1%
0.3%	1.8%	1.2%
3.7%	9.3%	12.0%
8.4%	40.2%	41.0%

of teeth of good structure (Hv_1)
of teeth slightly defective in structure ($M-Hv_1$)
of teeth defective in structure ($M-Hy$)
of teeth very defective in structure ($M-Hy_3$)

of teeth of good structure
of teeth slightly defective in structure
of teeth defective in structure
of teeth very defective in structure

From these figures the gradual decrease in percentage of teeth free from caries and increase in percentage with extensive disease as the structure deteriorates is apparent in each group, but there is a great difference between the institutional group and the other two in the proportion of non-carious and severely carious teeth associated with the more severe grades of structural defect (M-Hy₂ and M-Hy₃). The possible significance of these findings will be discussed later.

in the LCC schools. The extraction rate was highest (9.6%) in the LCC schools, next highest in the private schools (6.3%), and lowest (2.9%) in the institutions.

Staining of Surface Enamel or of Films on the Enamel

A record was made of the incidence of superficial staining of the teeth, so often seen in children, and it was found in all three groups (see Table VIII) that in those children with some or all of their teeth showing black or dark-brown

TABLE V—Incidence of Caries in Teeth with Varying Grades of Structure

	Private schools	34	38.2	12	0.0	42	35.1
	LCC schools	165	62.4	24	20.8	101	52.5

NOTE—(a) This table does not include the few teeth shown under the heading Hy unclassified in Table III. (b) In some grades of structure the numbers of teeth are relatively small and the percentage differences between the groups may thus be exaggerated.

The proportion of carious teeth among those classified as grossly hypoplastic (G-Hy) varies considerably, but is not generally nearly as high as that for the M-Hy₃ group (see Table V).

Arrest of the Carious Process and Treatment of Teeth

In charting the incidence of arrest, only teeth in which the carious area had become definitely hard, though not necessarily smooth and polished, were recorded as showing this phenomenon. Partial arrest was ignored. Under these conditions the percentages of carious teeth showing arrest of the disease were about the same in the institutions and LCC schools, but lower in the private schools, as is seen in Table VI. On the other hand, there was, as Table VII

shows, there was less caries than in those with no stain or with green stain. Most caries occurred in children who had some green stain. The relation between these stains and the incidence of caries has been discussed by a few

TABLE VIII—Amount of Caries in Relation to Superficial Staining of Teeth

Children with	Percentage of Carious Teeth			ACF		
	Inst	Private Schools	LCC Schools	Inst	Private School	LCC Schools
No stain	11.5	12.9	23.1	0.21	0.25	0.48
Black and dark brown stains	5.7	2.9	15.4	0.11	0.05	0.39
Green stain	20.2	22.5	33.0	0.39	0.46	0.69

other workers, including Pedersen (1946), who also observed that children with black stains were on the average less affected with dental caries than children without such stains on their teeth, and that those with green or yellow stains seemed to be more susceptible to the disease.

Discussion

An account has been given of the dental condition of the deciduous teeth of three groups of 5-year-old children examined in 1945, one group residing in institutions and the other two living at home and attending private schools and LCC schools.

The first fact observed in this survey was that in the institutions 66.1% and in the private schools 54.7% of the children were free or almost free from caries, whereas in the LCC schools the proportion in this category was of quite another order—namely, 28.1%. It was clear, therefore, either that there was some much more powerful protective factor against caries at work in the children in institutional and private schools than in those at the LCC schools—and if this was so it appeared to be even more potent in the first than in the second of these groups—or that in the children attending LCC schools there was some more powerful caries-producing factor in action.

TABLE VI—Teeth Showing Arrest (Spontaneous Healing?) of the Carious Process

LCC schools	3,545	9.6	2.8	2.4	14.8

* The figures in these columns would have been slightly higher if the extracted teeth had been excluded from the total numbers in the second column.

shows, far more treatment, especially that taking the form of fillings among the children attending private schools than among the other two groups. 18.5% of carious teeth being filled, as against 4.7% in the institutions and 2.4%

Before discussing the possible reasons for these differences between the groups further details must be considered. When the teeth themselves, as opposed to the dentition as a whole, are taken into account, and when structure is pitted against caries, some interesting facts come to light. For instance, in the institutions 32.3% of the teeth were of good structure (Hy₀), in the private schools 54%, and in the LCC schools 38%. The relationship between the groups was quite different when the incidence of caries was considered, since in the institutions 10.5% of the teeth were carious, in the private schools 14.2%, and in the LCC schools 26.5%. Thus, whereas by far the best dental structure was found in the private schools and the worst in the institutions, the latter had the lowest incidence of caries. In the LCC schools the structure of the teeth was rather better than in the institutions, but the caries incidence was very much higher than that of either of the other two groups.

Moreover, though in each group of children the better the structure the less the caries, yet for any given grade of structural defect there were fewer teeth with caries among the institutional children than among those in the other groups. For instance, in examining the molars it was found that

In grade M Hy₁

8.6%	were carious in the institutions
20.6%	" " " " private schools
25.0%	" " " " LCC schools

In grade M Hy

29.8%	were carious in the institutions
56.8%	" " " " private schools
66.5%	" " " " LCC schools

In grade M Hy₂

58.2%	were carious in the institutions
89.6%	" " " " private schools
92.3%	" " " " LCC schools

Similar differences between the groups could be quoted for other types of teeth.

The incidence of arrest of the carious process was rather lower in the private schools than in either of the other groups, where the results were about the same.

In view of the hypothesis, based on previous investigations by one of us and confirmed by colleagues, that the better the structure of the teeth the more likely they are to resist attack by caries, these results were clearly in the nature of a challenge, since it was found, in short, that (a) in each of the three groups the ordinary rule held—namely, there was a direct relation between structure and incidence of caries—but (b) comparing the three groups of children one with another the opposite conditions appeared to exist, for the children in the institutions, with the worst structure, had the least caries.

In comparing first the institutional and the private school children, there are two outstanding facts to be explained in the somewhat anomalous results of the survey. (1) Why was the structure of the teeth of the private school children better than that of the institutional children? and (2) Why in the teeth of the institutional children, which were worse formed, was there less caries than in the better-formed teeth of the private school children? It is necessary in this case to work on the basis of what is known, and, as previously mentioned, the two points that have been established are (a) that diets of high calcifying qualities in the pre-eruptive stage—that is, in pregnancy and lactation of the mother and in the early life of the child—produce better-formed teeth than diets poorer in this respect, and (b) that these same diets when given after eruption suppress, to some extent at least, the development of dental caries and tend to arrest the disease if present. Thus we have some of

the same factors at work in the pre-eruptive and the post-eruptive stages, but in the pre-eruptive period the effect of the diet is to control the structure of the teeth and in the post-eruptive to influence the development and course of dental caries. The problem, however, is not as simple as it looks because, clearly, the better-formed teeth resulting from the high calcifying diet of the pre-eruptive period will in themselves be more resistant to dental caries than badly formed teeth when both are exposed to the same post-eruptive diet. The teeth under examination in this work are the deciduous set, and since their calcification begins at about the twentieth week of foetal life and eruption is more or less complete when the child is about 2 years old, it is during this period that the type of feeding must control the actual structure of the teeth. Since, however, the lower incisors begin to be erupted at the age of 6 months the period from six months onwards must also be regarded as a post-eruptive age for an increasing number of deciduous teeth. After about two years the environmental effects would be wholly post-eruptive, while before six months the effect can be regarded as wholly pre-eruptive.

To explain the better-formed teeth of the private school children as compared with those of the institutional children, it is necessary to show that the diet of the former in pre-natal and early life was better from the point of view of calcifying properties than that of the institutional children during the same period of development. While actual proof cannot be given, we do not doubt that this is in fact the case, though the levelling up of the nation's dietaries that has taken place during recent years and particularly during the war, has probably made this difference less than it used to be. Indeed, if this were to-day only a question of the well-to-do mother *versus* the poor mother, increased facilities for getting protective foods, either free or at a cheap rate, are now so great that big differences might not be expected. The children, however, who become the responsibility of an institution are recruited largely from unsatisfactory homes where the mothers are often less well informed and more neglectful of their children, either from force of circumstances or because the children are unwanted. It is to be expected therefore, that so long as they continue to live under such conditions the children will be less well fed from the point of view under discussion than their contemporaries in better circumstances who will ultimately attend private schools.

As a class the well-to-do mothers are more intent on following medical advice during pregnancy and lactation than the mothers of the institutional children, and this advice nowadays usually includes an injunction to drink plenty of milk and to add cod-liver oil and other sources of vitamin D to the diet. Again the children of the former, when weaned, are more likely to be fed in early life according to the same principles. From all points of view, therefore, it might be expected that the teeth of the private school children would be of better structure than those of the institutional children. When, however, we turn to the post-eruptive stage matters are not the same. As the children of the well-to-do mother grow older there is a tendency for them to become more pampered and for dietary preferences to be considered. If for instance such an item as milk or eggs is disliked it may be omitted and the diet generally becomes of lower nutritional and calcifying quality. Sometimes, too, the daily dose of cod-liver oil or other preparation may be missed solely because parents or nurses do not like it or because they are careless in giving it to the children. In other words, the post-eruptive is often not so good as the pre-eruptive dietetic condition of children of this class. When, however, we consider the institutional children the matter is different.

in entry to an institution relatively neglected children come under conditions where feeding arrangements are regular and the diet is generally of a high quality from a nutritional standpoint—and incidentally from the point of view of calcification, as visits to institutions will confirm. This is due largely to the steadily increasing interest in the welfare of these children during recent years, but partly to wartime stringency. It is known that priority supplies, including milk, eggs, and cod-liver oil for institutional children, are regularly obtained. Moreover, it is almost certain that they are consumed, since individual likes and dislikes, which tend to disrupt the feeding arrangements of children of well-to-do mothers cannot be considered in a large community.

Such a state of affairs as that outlined above would in our opinion account largely for the otherwise anomalous findings in the institutions and private schools.

So far as could be judged from evidence kindly supplied by teachers in the various schools and by health visitors, the children attending L.C.C. schools would, on the average, be in a position in regard to diet intermediate between those at the private schools and those in institutions during the period of tooth development, although nearer the latter than the former, but in the post-eruptive years they would probably tend, because of the financial status of their parents and for other reasons, to be in a somewhat worse position than the private school children, though from the standpoint of this survey they would be subject to similar disabilities in regard to dietary likes and dislikes. If this were so, it would explain the fact that the structure of the deciduous teeth of these children was not nearly as good as that of the private school group, though somewhat better than that of the institutional children, and that their caries incidence was greater than that of either of the other two groups.

In this discussion only those environmental conditions—and especially the calcifying qualities of the diet—which have been established by experiment as influencing dental structure and incidence of caries have been considered. They seem to explain the facts as described. At the same time there are certainly other factors at work influencing the incidence of caries, about which we have no certain knowledge. It is said that fluorine is an important anti-caries factor, and, in England, Maldon is cited as a typical example. Here the fluorine content of the water is high and there is stated to be little dental caries compared with that in other parts of the country. In 1945 one of us (Counmoulos, 1946) found only 11.2% of deciduous teeth carious in 5-year-old children attending public elementary schools in that district—about the same proportion as was found in the present survey in the institutional children, few if any of whom were born or reared in Maldon. Again, the percentage of carious teeth in the private school group was not very much higher than that of the Maldon group. In the Maldon teeth, as in the three groups reported here, there was a direct relation between caries and M-hypoplasia, suggesting that the small amount of caries was again largely the result of the good structure rather than the influence of the fluorine in the water, although it seems that fluorine probably plays some part in the sequence of events.

Other possible factors affecting the initiation or prevention of caries, such as the effect of carbohydrates, the question of dental treatment, and the influence of tooth-brushes, have been considered in earlier publications (Mellanby and Counmoulos, 1944, 1946) dealing with the incidence of dental caries among school-children and will not be discussed here, as such discussion would at present lead only to negative conclusions. Still, the condition of the teeth of the institutional children as regards caries is,

in view of their defective structure, remarkable, and if there are secrets yet to be discovered which can fully explain these results, as there almost certainly are, every effort should be made to reveal them.

Summary

A description is given and a comparison is made of the dental condition in 1945 of three groups of 5 year old children: one residing in institutions and the others living at home and attending private schools and L.C.C. schools.

The proportion of children free or almost free from caries was greatest in the institutions, somewhat less in the private schools, and very much less in the L.C.C. schools.

Examination of the individual teeth revealed that, whereas the dental structure was by far the best in the children attending private schools and worst in those living in institutions, caries incidence and extent were lower in the latter than in the former. In the L.C.C. school group the structure of the teeth was slightly better than in the institutional group but far worse than in the private school group and the incidence and the extent of caries were the highest of all.

Although there was a direct relation between the structure of the teeth and the incidence and extent of caries among children of each group—that is to say the better the structure the less the caries—this did not hold between children of the different groups: thus in the institutional group teeth of a given grade of structural defect had much less caries than teeth of the same structure in either of the other two groups.

The incidence of arrest of the carious process was approximately the same in the institutions and L.C.C. schools and rather lower in the private schools.

In each group of children black or dark-brown superficial staining of the teeth appeared to be associated with a lower incidence, and green staining with a higher incidence, than the absence of stain.

Possible reasons for the striking contrasts between the groups of children in regard to their dental structure and caries incidence and extent are discussed, and it is suggested that the calcifying properties of the respective diets at different periods both pre-eruptive and post-eruptive, are an important key to the situation.

Surveys of this kind are possible only with the good will and co-operation of many people. We should therefore like to acknowledge our great indebtedness to the following, among others: (1) the proprietors, head teachers, and assistants of the private schools, who were always very kind and helpful in every way, and (2) the superintendents, matrons, and teachers in the institutions, who were ready not only to assist us directly, but in addition, to provide much information for which we asked. Our thanks also are due to Dr H. E. Magee, who kindly arranged our visits to the institutions, and to Mrs M. Kellev for her help generously given at all times.

Mr Hardman, Parliamentary Secretary to the Ministry of Education, announced in the House of Commons recently that the Foundation of Education Research was being asked to undertake an inquiry into the effects on children of various forms of punishment and rewards. Mr Hardman made this statement in reply to a question by Mr P. Freeman (Newport Lab.), who raised the question of corporal punishment of children in State schools. Mr Hardman stated that his Ministry had not advocated the use of corporal punishment, but public opinion had to be convinced that without it discipline could be maintained, and he personally deplored its continuance as a means of discipline. It is to be hoped that the committee of inquiry will include among its members representatives of the school medical service and of medical psychology, and that they will examine evidence from countries where corporal punishment is prohibited in schools.

A PENICILLIN-TREATED SERIES OF CASES OF OSTEOMYELITIS IN CHILDHOOD

BY

T TWISTINGTON HIGGINS, OBE, FRCS

Surgeon to the Hospital for Sick Children, Great Ormond Street

DENIS BROWNE, FRCS

Surgeon to the Hospital for Sick Children Great Ormond Street

AND

MARTIN BODIAN, MD

Pathologist to the Hospital for Sick Children Great Ormond Street

It is now well recognized that the use of penicillin in staphylococcal infections of the bones and joints of children has produced a most striking improvement in results. There is still, however, no agreement as to the dosage desirable or as to the surgical intervention which may be necessary in addition. In consequence the following account of work at the Hospital for Sick Children, Great Ormond Street, may be of interest, especially as in certain ways the treatment given has differed from that generally advised. The series described in the first two groups is a consecutive one without selection of any kind. In the third group, selection of cases is essential to the treatment advocated. An analysis of the cases is given in Tables I-III.

Group I Acute Osteomyelitis (31 cases)

Pathology

Age distribution—Sixteen were infants less than 1 year old, the others ranged up to 12 years. **Site of infection**—The lesions were in the long bones in 23 cases, other sites being the external cuneiform, the frontal bone, the sternum, and the maxilla—a curiously common site in infants. **Complications prior to penicillin treatment**—In four cases the infection spread from the bone to a neighbouring joint, causing a purulent arthritis. Soft-tissue abscesses occurred in 12 and septicaemia in three cases. Pneumonia preceded bone disease in three cases, otitis media and mastoiditis occurred in two cases, and femoral thrombosis in one case. **Duration of disease before admission**—Nineteen cases were of less than one week's standing, 8 up to four weeks, and 3 up to eight weeks.

Bacteriology—Coagulase-positive *Staphylococcus aureus* was grown from the blood stream in two cases, and from abscesses or joints in 12 cases. Haemolytic streptococcus was isolated from blood culture in one case and from abscesses or joints in three cases. Coagulase-negative *Staph. albus* was grown from an abscess in one case. All the micro-organisms isolated from these cases were highly penicillin-sensitive. In Case 5, however, a strain of haemolytic streptococcus, Lancefield group A, was ten times less sensitive than the standard Oxford strain of *Staph. aureus*. The child has made a complete recovery on the standard dosage of penicillin.

Radiology—Changes in the x-ray picture are not to be expected before the tenth to fourteenth day. Their extent varies greatly, mainly according to the time at which penicillin treatment is begun. As changes may be very slight, radiographs of the sound limb are essential for comparison. The earliest detectable change is loss of definition of the trabeculi or rarefaction of the affected bone. This may be accompanied or followed by the laying down of thin streaks of new bone outside the normal line of the periosteum. The changes may proceed no further and the bone return

to normal. On the other hand, very severe degrees of bony disorganization were seen, including in six cases the formation of apparent sequestra (see cases 8, 9, 12, 14, 17, 26). The severity of the radiological changes was out of all proportion to the clinical appearances and bacteriological findings. One point which has particularly impressed us is how these appearances will clear up completely without drastic surgery. It seems to us that these early radiological changes show disorganization of calcium deposition in a living bone rather than the actual death of that bone. There is need for further study of this most interesting point. In only one case (14) was a sequestrum removed. This was a particularly well defined and large one which occurred in the tibia after an infected intramedullary infusion. It was therefore not a typical case of osteomyelitis.

It should be noted, as regards both radiological and bacteriological evidence, that the abortive action of penicillin is so great that a diagnosis made on purely clinical grounds may never be confirmed in any other way.

Treatment

Penicillin Therapy—Treatment was begun immediately after collection of bacteriological specimens without waiting for reports. The dosage was 1,000 units per lb (454 g) body weight per twenty-four hours, given by intramuscular injection every four hours. In two cases this amount was doubled with no difference in the result. We consider that the safest course is to continue this treatment for at least three weeks, although in many of our cases it lasted for no more than a fortnight. Occasionally sterilization of the bone lesion may take nearly three weeks.

Surgical Treatment—An affected limb was immobilized in plaster in such a way that inspection of the affected region and aspiration could be easily performed. Immobilization was not prolonged much beyond the period of penicillin treatment, and movement was encouraged as soon as it was painless even in cases with marked radiological changes. In arthritis of the shoulder-joint the arm was merely bandaged to the side. Where our treatment differed from that generally followed was in 13 cases in which pus formed outside the infected bone. In all of these the pus was aspirated at intervals governed by the rate of re-forming pus. In most cases the aspiration was daily for the first few days, and after that at longer intervals when fluctuation could be detected. When pus was aspirated it was always replaced by injecting penicillin in a dose of 2,000 to 5,000 units. It is possible that this injection is unnecessary, but we feel that it can do no harm, and it appears reasonable to suppose that it may sterilize the cavity more rapidly than systemic penicillin alone.

In all cases—we must admit at first to our considerable surprise—pus finally ceased to form and healing was complete without sinus formation. The advantages of this conservative treatment are very great. It avoids that disastrous change in the outlook of the case which occurs when a single infection, controllable because penicillin-sensitive, becomes complicated by non-sensitive organisms. These secondary infections may come from anywhere, but two sources are impossible to eliminate when there is an open wound. The first is the skin, in which resistant organisms tend to develop under penicillin treatment. The second is the bowel, containing coliform bacilli, faecal streptococci and other insusceptible bacteria. Contamination from minute quantities of faecal material is unavoidable in certain situations, particularly in infants.

Results

Immediate clinical results were most striking. Many of these children were admitted in great pain, with high

temperatures, and some in a comatose state which before penicillin was a sign of grave danger to life. Within forty-eight hours, as a rule, the children were happy again, playing, sleeping, and eating well. Soft-tissue swellings, without the formation of pus, usually subsided in four or five days.

Bacteriological Results—The blood when infected was sterilized in four to seven days. The cavities of abscesses and infected joints were sterile in less than three weeks in all cases.

Functional results were perfect in all cases but one. Full movement and power in the affected limbs were obtained in from five weeks to five months, according to the severity of the condition. There have been no recurrences and metastases of the kind so common formerly. The one unsatisfactory case points a moral, as the treatment advised was not properly applied. Case 15 received at first only a seven-day course of penicillin, and the hip, though suspected, was not aspirated. After transient improvement the blood culture became positive again and the child gravely ill. Aspiration of the joint with a full course of penicillin cured the infection, but the hip was damaged beyond recovery and is now ankylosed.

Radiological results were the re-establishment of normal bone pattern. The final absence of gross bone deformity was very striking.

Group II Acute Suppurative Arthritis (4 cases)

Pathology—Coagulase-positive *Staph aureus* was isolated from the infected joints in two cases, and in one of these from the blood stream as well. No micro organism was isolated from the joint of another case, but the arthritis developed as a complication of meningococcal meningitis under treatment. Haemolytic streptococcus was grown from the joint in one case in which arthritis developed as a complication of recurrent mastoiditis.

Treatment—All these four cases were treated by conventional methods of aspiration and replacement by penicillin. A point of interest was the use in two cases of two needles, saline solution being injected through one to thin out unduly thick pus, which escaped by the other. There was no attempt at prolonged fixation or extension, the child being allowed to use the limb when it wanted to.

Results—All recovered completely.

Group III Chronic Osteomyelitis (5 cases)

Pathology—This group of five cases consisted of three of osteomyelitis of the rib, one of the os calcis, and one of the upper part of the ilium—all of the too familiar kind in which a discharging sinus leads down to bare bone, more or less necrosed. The selection mentioned earlier consisted in picking cases in which the infected bone tissue could be removed without damage to the functions of the body. This limits the method of treatment described to such bones as the ribs, the fibulae, the sternum, the os calcis, and the crest of the ilium. In widespread infections of bones difficult of access it is unsuitable.

Treatment—The infected bone was exposed and completely removed, taking with it a margin of healthy bone. All granulations were carefully scraped away and penicillin in solution or powder instilled. The wound was then sewn up completely, with the idea of avoiding contamination by penicillin-resistant organisms. Firm pressure was applied to it by means of an "elastoplast" dressing, and it was left untouched for a fortnight. There was no attempt to obliterate the cavity of the wound if this was difficult to do, the idea being to get healing by organization of a blood-clot sterilized by penicillin. Healing of this kind was obtained

first by Lister, who describes mixing blood and carbolic acid into a paste and using it to fill wounds

Results—When the dressing was removed healing in all cases was either complete or sufficiently advanced to shield the deeper parts of the wound from infection. All wounds were dry in three weeks from operation, and have remained so since for periods varying from nine months to two and a half years. It may be noted that no particular benefit has been observed to follow the local or general use of penicillin in cases in which all the infected bony and soft tissue could not be removed. Such sites of infection as the upper end of the femur or the vertebrae still remain most intractable once a communication, temporary or permanent, has been formed with the outer surface of the body.

Summary and Conclusions

Three series of cases are reported: 31 of acute osteomyelitis, 4 of acute suppurative arthritis, 5 of chronic osteomyelitis.

Of the acute cases 50% were in infants under 1 year old.

Dosages of penicillin were relatively small—1,000 units per lb (454 g) body weight per twenty-four hours for three weeks.

In acute osteomyelitis and arthritis surgery was confined to aspiration of pus. Immobilization was partial and for short periods.

Radiological changes observed were far less serious clinically than might have been expected from their marked character.

In suitable cases of chronic osteomyelitis excision of infected tissue and primary suture is advised.

Mortality was nil. Complete restoration of function occurred in all but one of the acute cases. There was apparent complete healing in all the chronic cases.

We wish to acknowledge the kindness of physicians and surgeons at the Hospital for Sick Children, Great Ormond Street, who have permitted us to include some of their cases in this paper. We are also much indebted to Miss Eileen Rawlings for her tireless clerical assistance.

Extensions to Joyce Green Hospital (L.C.C.), Dartford, including new wards to accommodate 120 beds, a new main operating theatre, and a nurses' home, were completed in 1939, but the formal opening by Mr A. Reginald Stamp, chairman of the Hospitals and Medical Services Committee of the London County Council, was delayed until April of this year. This was originally one of the three river hospitals under the control of the Metropolitan Asylums Board. The main hospital buildings were opened in 1903, following smallpox epidemics in the two previous years, to take the place of the Thames ships which were formerly employed as floating hospitals. Afterwards it was used for infectious diseases generally, and during the last eight years it has admitted general medical and surgical patients. As a war emergency hospital its previous accommodation of 986 beds was almost doubled. The wards newly constructed, however, were not brought into use during the war because the large amount of glass made them unsafe, and indeed the hospital suffered extensively and repeatedly from blast. The total cost of the new extensions is £134,000. One of the new wards houses neuro surgery and physiotherapy units and the other is for children. Ear, nose, and throat, ophthalmic and dental clinics have been established in the new premises. At the opening ceremony Mr Stamp said that the extensions were part of a great reconstruction programme for the Council's 76 hospitals, but he added that this was the last year that Joyce Green and all the other hospitals would be under L.C.C. control. At County Hall they were anxious that the hospitals should be transferred to the National Health Service as going concerns. Sir Allen Daley paid a tribute to the medical superintendent, Dr Maurice Mitman, the matron, Miss Vivian, and the staff at Joyce Green for the first-class medical and surgical work which had been done at the hospital throughout the war notwithstanding recurring air raid damage and continual danger.

REFRIGERATION ANAESTHESIA

BY

E. S. R. HUGHES, MD, MS, FRCS

Refrigeration anaesthesia for limb amputations was introduced into the Royal Melbourne Hospital towards the end of 1944. Since then 25 lower-limb amputations have been performed with the aid of this technique, and they are here reported. With one exception all the amputations have been through the lower third of the thigh. It is not possible to reduce results fairly to statistical form owing to the diverse nature of the patients' condition. In the table the predominant constitutional factor has been indicated as either "atherosclerosis" or "diabetes mellitus". Some of the former group have had accompanying cardiac failure, renal failure, or cerebral degeneration, some of the latter group have been admitted in a coma or semicoma, and all have had atherosclerosis to a varying degree.

The local condition that required amputation has varied, most frequently it was progressive gangrene of the foot or gangrene complicated by severe pain or infection. In addition there were two cases of popliteal thrombosis accompanied by severe pain, two cases of gross infection of ulcers of the leg causing deterioration of the general condition of the patient despite conservative measures, two cases with epithelioma of the leg, one of which was severely infected and had metastatic glands in the groin, and the other equally badly infected and complicated by a pathological compound fracture of the tibia and fibula, finally, there was one case of a mangled foot in a shocked patient aged 69 years.

Technique

The simplest technique has been used throughout this series; the more elaborate and costly apparatus employed by some clinics abroad has not been available.

The Ice—The ice has been procured from a city firm in 50-lb (22.68-kg) bags. It is already crushed when delivered, though sometimes the pieces have to be broken further before use. When packing a limb it was found that ice obtained on the previous day and kept at room temperature overnight was easier to handle than that obtained on the same day, because the sharp edges had become rounded off.

The Apparatus—Two methods have been used to retain the ice in position: a wooden box 40 by 10 by 10 in (100 by 25 by 25 cm) lined with galvanized-iron sheeting and drained at one corner, or two Mackintoshes held in position by long stout calico bandages or by a reversed single-limb cradle. Two bags of ice are required initially, and one or two daily for maintenance in cases of prolonged refrigeration.

The Procedure

There are three main sources of infection—the patient, the ice, and the surgeon and his staff. The ice cannot be sterilized, but by adopting the usual procedures with the patient and the operating team the danger of infection is lessened. The limb and pubic region are shaved and the patient is placed on a canvas sheet. The abdomen and affected leg are given the routine pre-operative preparation and covered with sterile towels, the limb is then ready for the application of the tourniquet and placing in the ice.

The tourniquet is not an essential requirement at any stage of the procedure and may be dispensed with altogether. A tourniquet—of soft rubber pressure-tubing—has been used here for reasons given below. The tourniquet is first sterilized either by autoclaving or by boiling. The former method is preferable as a firmer grip may be obtained on the dry tourniquet. After the operator has scrubbed and the limb has been elevated, the sterile tourniquet is applied as tightly as possible just above the site of proposed amputation. It may be held with a reef knot, with sterile Kocher's clamps or with sponge forceps. Occasionally the tourniquet has snapped some time after the application, hence it is wise to inspect it regularly.

TABLE III—Chronic Osteomyelitis

Extensions to Joyce Green Hospital (L.C.C.), Dartford, including new wards to accommodate 120 beds, a new main operating theatre, and a nurses' home, were completed in 1939 but the formal opening by Mr. A. Reginald Stamp, chairman of the Hospitals and Medical Services Committee of the London County Council, was delayed until April of this year. This was originally one of the three river hospitals under the control of the Metropolitan Asylums Board. The main hospital buildings were opened in 1903 following smallpox epidemics in the two previous years, to take the place of the Thames ships which were formerly employed as floating hospitals. Afterwards it was used for infectious diseases generally, and during the last eight years it has admitted general medical and surgical patients. As a war emergency hospital its previous accommodation of 986 beds was almost doubled. The wards newly constructed, however, were not brought into use during the war because the large amount of glass made them unsafe, and indeed the hospital suffered extensively and repeatedly from blast. The total cost of the new extensions is £134,000. One of the new wards houses neurosurgery and physiotherapy units and the other is for children. Ear, nose, and throat, ophthalmic and dental clinics have been established in the new premises. At the opening ceremony Mr. Stamp said that the extensions were part of a great reconstruction programme for the Council's 76 hospitals, but he added that this was the last year that Joyce Green and all the other hospitals would be under L.C.C. control. At County Hall they were anxious that the hospitals should be transferred to the National Health Service as going concerns. Sir Allen Daley paid a tribute to the medical superintendent, Dr. Maurice Mxman, the matron, Miss Vivian, and the staff at Joyce Green for the first-class medical and surgical work which had been done at the hospital throughout the war notwithstanding recurring air raid damage and continual danger.

REFRIGERATION ANAESTHESIA

BY

E. S. R. HUGHES, M.D., M.S., F.R.C.S.

Refrigeration anaesthesia for limb amputations was introduced into the Royal Melbourne Hospital towards the end of 1944. Since then 25 lower-limb amputations have been performed with the aid of this technique, and they are here reported. With one exception all the amputations have been through the lower third of the thigh. It is not possible to reduce results fairly to statistical form owing to the diverse nature of the patients' condition. In the table the predominant constitutional factor has been indicated as either "atherosclerosis" or "diabetes mellitus". Some of the former group have had accompanying cardiac failure, renal failure, or cerebral degeneration, some of the latter group have been admitted in a coma or semicoma, and all have had atherosclerosis to a varying degree.

The local condition that required amputation has varied, most frequently it was progressive gangrene of the foot or gangrene complicated by severe pain or infection. In addition there were two cases of popliteal thrombosis accompanied by severe pain, two cases of gross infection of ulcers of the leg causing deterioration of the general condition of the patient despite conservative measures, two cases with epithelioma of the leg, one of which was severely infected and had metastatic glands in the groin, and the other equally badly infected and complicated by a pathological compound fracture of the tibia and fibula, finally, there was one case of a mangled foot in a shocked patient aged 69 years.

Technique

The simplest technique has been used throughout this series; the more elaborate and costly apparatus employed by some clinics abroad has not been available.

The Ice—The ice has been procured from a city firm in 50-lb (22.68-kg) bags. It is already crushed when delivered, though sometimes the pieces have to be broken further before use. When packing a limb it was found that ice obtained on the previous day and kept at room temperature overnight was easier to handle than that obtained on the same day, because the sharp edges had become rounded off.

The Apparatus—Two methods have been used to retain the ice in position: a wooden box 40 by 10 by 10 in (100 by 25 by 25 cm) lined with galvanized-iron sheeting and drained at one corner, or two mackintoshes held in position by long stout calico bandages or by a reversed single limb cradle. Two bags of ice are required initially, and one or two daily for maintenance in cases of prolonged refrigeration.

The Procedure

There are three main sources of infection—the patient, the ice, and the surgeon and his staff. The ice cannot be sterilized, but by adopting the usual procedures with the patient and the operating team the danger of infection is lessened. The limb and pubic region are shaved and the patient is placed on a canvas sheet. The abdomen and affected leg are given the routine pre-operative preparation and covered with sterile towels, the limb is then ready for the application of the tourniquet and placing in the ice.

The tourniquet is not an essential requirement at any stage of the procedure and may be dispensed with altogether. A tourniquet—of soft rubber pressure tubing—has been used here for reasons given below. The tourniquet is first sterilized either by autoclaving or by boiling. The former method is preferable as a firmer grip may be obtained on the dry tourniquet. After the operator has scrubbed and the limb has been elevated, the sterile tourniquet is applied as tightly as possible just above the site of proposed amputation. It may be held with a reef knot, with sterile Kocher's clamps or with sponge forceps. Occasionally the tourniquet has snapped some time after the application, hence it is wise to inspect it regularly.

A bed of crushed ice about 4 in (10 cm) deep is made, extending from above the tourniquet site to beyond the foot. To ease the pain of the tourniquet application it is advisable to keep the leg encased in ice for a period of an hour before hand, in such circumstances the leg is lifted clear of the ice the tourniquet is applied, and the leg is lowered again and covered with ice. The head of the bed is raised on blocks to assist drainage of the ice. The patient is made comfortable and the rest of the body is kept warm. The period of time for which the limb is refrigerated depends on the relation of the local lesion to the general condition of the patient, if the former be the cause of depression of the latter, then by cooling the lesion to the approximate level of 5°C at which level metabolism is minimal, it becomes physiologically disconnected

operating table with the ice still in position, the surgeon and his team have scrubbed and are ready. A large canvas accommodated on a wheeled stand is moved to the foot of the table. The leg is elevated above the ice and the little swept into the canvas bag. The towels around the leg are removed, the area is given a final preparation by the surgeon and the operation proceeds as in cases with the usual forms of anaesthesia. To secure complete haemostasis the tourniquet is left in position until the surgeon orders its removal. There is no need to hurry through the operation, as good anaesthesia persists for an hour or more.

Certain special features of the post-operative period may be noted. The absence of any primary shock despite the fact that the patient remains fully conscious of his surroundings permits

Details of 25 Limb Amputations in which Refrigeration Anaesthesia was used

Case No	Age	Sex	General Condition	Local Condition	Remarks	Duration of Refrigeration	Result
1	60	M	Atherosclerosis	Gangrenous foot continued spread	Auricular fibrillation	3 hours	Discharged 4 months after operation. Gas gangrene second post-operative day.
2	83	M		Gangrenous foot severe infection	—	6 days	Discharged 5 weeks after operation. Convalescence uneventful.
3	78	M		Huge infected ulcer of leg	Amputation of other leg 6 years previously	4	Death 12 days after operation. Bronchopneumonia.
4	70	M		Gangrenous foot intractable pain	Cerebral degeneration	3	Discharged 8 weeks after operation. Mild secondary shock wound infection.
5	85	M		Gangrenous foot intractable pain	—	3 hours	Death 5 days after operation. Severe secondary shock followed by bronchopneumonia.
6	67	F		Grossly infected ulcers of leg	Nephrectomy 10 years before. Poor renal function.	10 days	Death 8 days after operation. Renal failure.
7	65	M		Gangrenous foot severe infection	—	7	Death 17 days after operation. Severe septic stump.
8	88	M		Gangrenous foot continued spread	Cardiac failure	7	Death 8 days after operation. Renal failure.
9	78	M		Gangrenous foot intractable pain	Paralysis agitans	6	Death 24 hours after operation. Cause undetermined.
10	73	M		Popliteal thrombosis	Advanced cardiac failure	7	Death 14 days after operation. Cardiac failure bronchopneumonia.
11	78	F	Diabetes mellitus	Gangrenous foot severe infection and pain	—	8	Death 2 days after operation. Bronchopneumonia.
12	74	F		Gangrenous foot continued spread	—	4	Discharged 4 weeks after operation. Convalescence uneventful.
13	73	F	Atherosclerosis	Epithelioma of leg severe infection	—	3 hours	Discharged 4 weeks after operation. Convalescence uneventful.
14	63	F		Gangrenous foot severe infection	Diabetes mellitus suspected	3	Death 9 weeks after operation. Cardiac failure, stump healed.
15	80	F	Diabetes mellitus	Gangrenous foot severe infection	—	3 days	Discharged 8 weeks after operation. Mild secondary shock and wound infection.
16	78	F		Gangrenous foot continued spread	Carcinoma of common bile duct and metastasis in liver jaundice	3 hours	Death 4 weeks after operation. Stump healed.
17	56	F		Gangrenous foot severe infection	Coma	3	Death 6 days after operation. Remained moribund bronchopneumonia.
18	68	F		Popliteal thrombosis	—	3	Discharged 5 weeks after operation. Convalescence uneventful.
19	73	F	Atherosclerosis	Gangrenous foot intractable pain	Cerebral degeneration	3	Death 3 weeks after operation. Cerebral thrombosis stump healed.
20	69	F	Diabetes mellitus	Gangrenous foot severe infection	Semicoma	9 days	Discharged 6 weeks after operation. Convalescence uneventful.
21	74	F	Atherosclerosis	Epithelioma of leg severe infection	Marked debility	3 hours	Discharged 8 weeks after operation. Convalescence uneventful.
22	76	F		Gangrenous foot severe infection and pain	—	2 days	Discharged 5 weeks after operation. Convalescence uneventful.
23	59	F	Diabetes mellitus	Gangrenous foot severe infection	Semicoma	3	To be discharged. Convalescence uneventful.
24	75	F		Gangrenous foot severe infection	—	24 hours	To be discharged. Convalescence uneventful.
25	69	M	Atherosclerosis	Mangled foot	Shock	3	Discharged 10 weeks after operation. Wound infection.

from the body. Therefore if the patient is suffering from severe pain or from toxæmia the affected area of the limb is refrigerated for several days without a tourniquet several hours before the operation, as in all other cases the refrigerated area is extended by increasing the amount of ice to just above the tourniquet level. The minimum time for which a limb may be safely refrigerated before operation varies from two to three hours.

It is not essential to give any pre-operative medication, but those who are apprehensive may have injections of morphine—1/8–1/4 gr (8–16 mg). In those cases of this series requiring such sedation the drug was given before the application of the tourniquet. The complete relief from a severe and persistent pain in the foot has been a most noticeable feature of refrigeration.

Transport to the theatre with the ice in position has not been difficult, as the patient and the ice-container have previously been placed above canvas. The patient is lifted on to the

him to continue his meals without interruption. Systemic sulphonamide therapy has been used in all cases post-operatively and has been a useful measure in avoiding or lessening local and pulmonary infections. A careful watch is maintained on the chest, a cold wet bed, so often seen in the pre-operative period, predisposes to infection. After amputation the stump may be kept cool with ice bags. This has not been done in the present series for two reasons: first, the results have seemed satisfactory without such cooling; secondly, a dry bed after operation is essential. A thick layer of cotton wool acts as a moderately satisfactory insulating dressing. Stitches have been removed from the wounds at the same time as after operation under the usual anaesthetics.

Complications

Shock—Primary shock did not occur, but secondary shock was not absolutely prevented, though it was minimized. It would probably have been still further decreased

f the post-operative cooling had been satisfactory in all cases. But it was found that ice without waterproof bags was difficult to handle even by the experienced individual, and post-operative cooling so often meant an icy-cold wet bed, with all its attendant disadvantages, that this step was omitted.

Bronchopneumonia—This was the cause of death of five patients. Wet sheets and blankets, caused by leakage from the ice despite elaborate precautions, were an important contributory factor. The most certain method of prevention is the use of ice-bags or electrically controlled apparatus in place of the bare ice. The ability of the patient to move about and sit upright in bed from the outset and to continue with nourishment has partially neutralized the effects of this unfortunate complicating wet bed.

Local Complications—Surrounding the limbs with ice has not caused pain. The tourniquet occasioned temporary discomfort in some who had not been previously cooled at the site of application. In all cases the operation has been performed painlessly, and post-operative pain in the stump has not been a feature. No delay was observed in the healing of the stump except when infection supervened. There was no evidence of any sloughing of the flaps despite amputation below a tourniquet in this series (Perlow, 1944). The incidence of infection in this series actually appeared to be lessened, so conforming with published results. In the first case gas-gangrene developed, but at the same time there was a case of similar infection in hospital which was also a sequel of an amputation, but not a refrigeration amputation. Refrigeration has not increased this form of infection despite fears to the contrary (Kirtz, 1944). Cultures were made from ten consecutive specimens of ice, but in no case were pathogenic bacilli isolated aerobically or anaerobically.

Miscellaneous Complications—Two cases are noted in the Table as resulting in death from renal failure. At necropsy both cases showed advanced renal disease of long duration. No ill effects were observed from the use of the tourniquet or cold temperatures. There were no cases of thrombosis or embolism, nor were there any cold sensitive stumps as might perhaps have been anticipated. The skin of the amputated leg sometimes showed slight scaling when refrigeration had been prolonged for some days, but only the most superficial of the epidermal layers were involved.

Discussion

Since the first large-scale trial of refrigeration anaesthesia in America in 1941 (Crossman *et al.* 1942) many independent clinical reports have been published abroad with a uniform expression of satisfaction at the reduction of mortality in poor-risk cases (Batalha, 1946, Cayford and Pretty, 1945, Hinchey, 1944, Lobachev, 1946, McElvenny, 1942, Massie, 1944, Mock and Mock, 1943, O'Neil, 1944, Richards, 1944, Yudin, 1945a, 1945b).

The very foundation of the technique is the application of cold temperatures with or without a tourniquet, and since these have been regarded with suspicion and disapproval a brief discussion is necessary.

The temperatures used in refrigeration anaesthesia are not freezing temperatures. They are never less than 0° C. The skin, by virtue of its capacity for supercooling, does not freeze unless the temperature is below -22° C (Lewis and Love, 1926, Lewis, 1941). Admittedly moisture on the skin reduces the degree of supercooling, but freezing never occurs at 0° C. Cooling the skin to 0° C, or even supercooling to a considerable extent, very rarely causes injury (Lewis and Love, 1926). Temperatures resulting in frost-bite are much lower than those used in refrigeration

anaesthesia (Lewis, 1941, Greene, 1941). Immersion-foot lesions have been reported in survivors adrift for several days in warm sea-water (White and Scoville, 1945). In these circumstances, however, the circulation and general resistance are depressed by starvation, exposure, and possibly other injuries. Cramped or dependent positions, tight clothing, or other local factors embarrass the circulation still further. Finally, the deleterious effects of moisture in the causation of thermal damage are implied in the term "immersion". In refrigeration anaesthesia the general condition is maintained throughout so far as is practicable, the circulation within the limb is either completely stopped or is maintained at maximum efficiency, the unfavourable effects of moisture have not been observed with cracked ice draining freely.

The tourniquet is not essential for adequate anaesthesia (Cayford and Pretty, 1945), but its employment is advised for the following reasons. (a) When the inflow of warm blood is stopped the tissues can be chilled thoroughly and rapidly. Radical lowering of the temperature in a limb is practically only obtainable with a tourniquet, unless there is gross pathological obstruction of the arteries. With the thorough reduction of the temperature that is possible with a tourniquet all protoplasmic activity is abolished, primary shock is non-existent in amputations on such limbs. (b) When the return flow of cold blood is stopped reflex vasoconstriction is prevented in various parts of the body. This might be harmful in cases of Buerger's disease and other conditions resulting in ischaemia to a part (Neller and Schmidt, 1944).

But the tourniquet is regarded with misgivings and its prolonged application with concern. The correctly applied tourniquet, however, is not as dangerous as believed (Allen, 1945c). The tourniquet that serves best is good soft rubber tubing (Allen, 1944), hard inelastic materials create trouble either through looseness or through crushing. In the leg, unlike the thin upper limb, very strong tension seems to cause no harm. The time factor has been greatly misjudged by surgeons in the past. Hinman (1945) has reviewed the factors that limit the duration of application. The most important of these are anoxia in the tissues distal to the tourniquet and shock on its removal. But the cold temperatures reduce to a minimum the oxygen requirements, and amputation of the distal tissues largely avoids the danger of shock (Allen, 1938, 1939, 1944, 1945a, 1945b, Allen *et al.*, 1942a, 1942b, 1943, Brooks and Duncan, 1940, Wilson and Roome, 1936).

The most convincing evidence, both experimental and practical, supports refrigeration as a valuable form of anaesthesia and as a sure means of excluding a constitutional depressant (Mock, 1946). However, I do not agree with those who claim that all patients to be subjected to amputation should be so anaesthetized (Crossman and Allen, 1946). Anaesthetists in England have attained a remarkably high standard, and few patients suffer from anaesthetics skilfully administered. Nevertheless it is submitted that there are certain bad-risk cases in which life can be saved by resort to this technique.

Summary

Twenty five consecutive cases of amputation under refrigeration anaesthesia are reported. The details of individual cases are provided in the Table.

The method used in this series is described. The simplest technique has been used.

Bronchopneumonia was the most frequent complication.

Recent opinions concerning the effects of cold temperatures and tourniquet application are discussed.

It is submitted that this method be reserved for certain bad risk cases.

I wish to express my gratitude to the Royal Melbourne Hospital Committee for permission to publish this series and to Mr J B Turner and Mr Paul Jones for allowing me to study their cases

PRIMARY MALARIA IN LONDON CHILDREN

REPORT OF TWO CASES

BY

C BLAXLAND LEVICK, MB, FRCP

Physician St George's Hospital and Victoria Hospital for Children

AND

M E MacGREGOR, MD, MRCP

Paediatric Chief Assistant St George's Hospital and Victoria Hospital for Children

Two cases of primary malaria in London children have been discovered in one out-patient clinic within the space of a few months. They are reported now as a reminder of the necessity for keeping this diagnosis in mind when confronted with cases of unexplained fever in children who have never been out of this country

Case 1

A girl aged 6 attended the Victoria Hospital for Children as an out patient on May 9, 1946, with a history of loss of appetite and a heavy head cold for one week, nocturnal delirium for 48 hours, and vomiting fever, and headache for 24 hours. At the time of examination a severe rigor was taking place the oral temperature was 102° F (38.9° C), but there were no other abnormal physical signs. She was admitted to hospital immediately. Her temperature remained about 100° F (37.8° C) for the first 48 hours after admission, then fell to normal for 12 hours and thereafter showed spikes of 100°–104° F (37.8–40° C) on alternate days each rise occurred between 1 and 8 p.m. and was preceded by a rigor lasting about half an hour. She complained of frontal headache and became confused at the height of each paroxysm. Between attacks her temperature was normal and she was alert and well. At first all investigations including three thin blood films, proved negative. The spleen tip became palpable on May 24. Quinine sul-

phate, 15 gr (1 g) daily, was started empirically the same day and the pyrexia ceased at once. Quinine was discontinued after 10 days but on June 6 coincident with another rigor and a pyrexia of 104° F, many benign tertian ring forms were demonstrated for the first time in a thin blood film. Quinine bihydrochloride, 12 gr (0.8 g) daily, with pamaquin, 15 mg daily, was given for another ten days. Progress was uneventful apart from one sharp rise of temperature on June 12. A blood film on the 14th showed many red cells containing Schüffners dots, but no parasites were seen then or thereafter. The spleen could not be felt after June 10. After two more courses of quinine, the patient returned home on Aug 15 and remained symptom-free until Dec 10, when her original symptoms were repeated. On Dec 17 she was readmitted to hospital. A course of quinine and pamaquin was administered, and she has since continued free from symptoms.

Her past medical history revealed nothing of importance. The father, a Cypriot, came to England from Cyprus 15 years ago, and is now a waiter in London. The mother has never been out of England. Both parents and two siblings are well. No history of malaria was ascertained. There has been no contact with any relative from overseas. The patient remained in Worcestershire from infancy until September, 1945 (during the war there was a large American military camp near her dwelling place) went to Welling, Kent, for six months, and then moved to Pimlico, where the family now live.

The medical officer of health for the City of Westminster states that in the past year, apart from relapsed cases in military personnel treated in hospital, no other case of malaria has been reported to him.

Case 2

A boy aged 2 was seen as an out-patient at the Victoria Hospital for Children on Sept 26, 1946, with three weeks' history of a daily shivering attack between 1 and 5 p.m., not missing a single day. During these he was stated to be at first cold, blue, and shivering then burning hot, then sweating and, finally, half an hour later, quite well again, the whole attack lasting about three hours. There was no vomiting.

He was admitted to hospital immediately, and was afebrile. He was a well nourished child of 28 lb (12.7 kg), with shadowing under the eyes and a yellowish pallor of the skin. The spleen was palpable two fingerbreadths below the costal margin. There were no other abnormal physical signs. At 3 p.m. of the day of admission and on the day following he had a rigor the temperature rising to 103° F (39.4° C). A large number of benign tertian malarial ring forms were seen in a thin blood film on Sept 27. A blood count showed red cells, 3,000,000 per c mm, haemoglobin, 42%, white cells, 8,400 (polymorphs 50% lymphocytes, 45%, monocytes, 3%). He responded well to oral quinine and has had no recurrence since being discharged home on Oct 23.

The patient is an only child. The parents are separated neither has ever been abroad. The father was in the R.A.F. and was under investigation in 1941 for unexplained fever, he still has occasional fever, but has refused to allow examination of a blood film. Father and child were in close contact during the first six months of 1946. Apart from a grandfather who had malaria in 1918 without subsequent relapse, there is no known contact with a malarial case. His only previous illness was bronchitis. He was born in Scarborough and was taken to London when 2 weeks old, to Bristol when he was 6 weeks and back to London in October, 1945. Since then he has lived in Chelsea, apart from a visit in August 1946 to the Isle of Sheppey, where the whole family were severely bitten by mosquitoes.

The medical officer of health for Chelsea states that no other case of primary malaria has been reported in his area during 1946 and the medical officer of health for the Isle of Sheppey gives the same report. Anopheline mosquitoes however are known to be present in the Isle of Sheppey.

Discussion

Unfortunately the source of infection is not absolutely clear in either case. It seems unlikely that primary malaria would remain symptomless for more than a week or two in a child in England. Therefore infection must have occurred

within a few weeks of the first symptoms, unless the attacks were relapses of an undetected primary infection months or years before. In neither history is there any suggestive record of undiagnosed fever. Case 1 had moved from Kent to London eight weeks before developing symptoms. The only known contact with potentially malarial subjects ended six months before that, when she left the neighbourhood of the American military camp, but no symptoms were noticed during or shortly after that period. It is most probable that she was bitten in Welling, Kent, by an anopheline mosquito infected by a Service case from overseas.

Case 2 must similarly have contracted the infection either in the Isle of Sheppey in August or in Chelsea thereafter. While in the Isle of Sheppey he was known to have been bitten by mosquitoes, which could have been anopheline. It is possible that his father's bouts of fever are malarial, although he was never overseas, and, while unlikely, it would also be possible during a month's holiday for infection to be transferred to the child. The mother was also bitten, but apparently was not infected. It is more probable that the anophelines in the Isle of Sheppey acquired malaria parasites from a local resident infected overseas during the war. It is most unlikely that the infection in either case was contracted in London, where the density of population would lead to the recognition of more than one or two cases if infected mosquitoes existed in any area.

Although *Anopheles maculipennis* is widely distributed in Great Britain, indigenous malaria during this century has been confined almost entirely to the south-east seaboard of England and to the Thames Valley (Min Hith Memo, 1943). Towards the end of the 1914-18 war numerous cases of malaria occurred among children and adults who had never left this country. In 1919, 300 cases of indigenous malaria were notified, since then the numbers have fallen fairly steadily (7 cases in 1945), the largest number occurring in north-east Kent. In addition to the two cases described above, Dr P. G. Stock informs us that five other cases of indigenous malaria (all adults) were notified during 1946, including two from Oxford (Stevens and Blackman, 1946) and one from Kent. There is no record of primary malaria having been contracted in London for over 25 years.

Medical Memoranda

Peptic Ulceration in Identical Twins

The literature relating to peptic ulceration in identical twins was reviewed by Riecker (1946) when he reported the occurrence of duodenal ulceration in 20-year-old identical female twins. He found no reference to any such cases before 1935, but since then Schindler (1935) has recorded the occurrence of gastric ulcer in 39-year-old identical twin brothers, and von Mentzingen (1935) and McHardy and Browne (1944) have reported cases of duodenal ulceration in 20-year-old identical female twins and 28-year-old identical male twins. The family history was not included in McHardy and Browne's report, but in the other three peptic ulceration was present in one or other parent.

A fifth case of peptic ulceration in 30-year-old identical male twins can now be added to the series. These twins were born on Sept. 8, 1916. The onset of symptoms in Case 1 was followed within a month by the death of the other from repeated haematemesis. When they were first examined there was no history of any gastro-intestinal disorders in either

parent or in the remaining nine siblings (six females, aged 34, 33, 26, 24, 21, and 19 years, and three males, aged 28, 23, and 18 years), all of whom were alive and well. Since then the two youngest members of the family have both complained of indigestion, and at the time of writing there is radiological evidence of duodenal ulcer in the youngest male. The evidence that these twins were identical is based on the fact that they were identical in appearance and that there was only one placenta.

CASE 1

The patient, a leading aircraftman, aged 30, had been in the R.A.F. for 4½ years, and was in medical category A1. He was admitted to hospital in Antwerp under my care on Oct. 1, 1946, with a six weeks history of abdominal pain. Following the death of his identical twin on Sept. 9, 1946, he became acutely depressed and anxious, and immediately experienced a pronounced intensification of his pre-existing symptoms. The pain was localized to the right upper quadrant of his abdomen, and did not radiate to any other site. It occurred at irregular intervals throughout each day, and not at any definite time after meals, and lasted on the average for one half to one hour. Of late it had become worse when hungry, being then relieved by food, and had awakened him between 2 and 4 a.m. The pain bore no relation to the quality of food taken, and was not associated with either nausea or vomiting. His appetite was poor, but he was not afraid to eat. He did not think that he had lost weight. He had taken no alkalis. At the time of onset of symptoms he passed three or four fluid stools daily for three days, but he had no fever, and, so far as he knew, the stools contained neither blood nor mucus. He had had no serious illnesses in the past. His occupation entailed regular meal-times. He smoked 10 to 15 cigarettes a day, and during the last few weeks had consumed some 6 to 7 pints (3.4 to 4 litres) of beer daily.

On examination he was co-operative and intelligent, yet he appeared tired and apathetic. The only abnormalities present were that all his premolars and molars were deficient, though no denture was worn, and examination revealed some localized rigidity and tenderness below the right costal margin, extending 1½ to 5 in (3.8 to 12.5 cm) from the midline. The red cell count was 4,130,000 per c.mm., haemoglobin, 92% (Haldane), and colour index, 1.11. The benzidine test for occult blood was positive on three consecutive examinations. A test meal showed a highly acid resting juice, with a rapid rise in the total and free acidity, and the presence of starch indicated a delay in emptying. A barium meal examination (Capt. W. N. Thompson) revealed that the stomach was orthotonic, with a moderate increase in the mucosal relief. The duodenum showed retraction (Åkerlund) deformity with a small crater on the antero-lateral wall of the cap.

CASE 2

The twin brother of Case 1 was admitted to the Royal Salop Infirmary, Shrewsbury, on Sept. 6, 1946, having recently been released from the R.A.F. after 3½ years service in the Middle East. For the last four or five years he had suffered from indigestion and attacks of mid-abdominal pain after meals. These attacks lasted on the average for six to seven weeks, and were then followed by long periods of complete freedom. During the 24 hours preceding admission he had complained of indigestion, had vomited food only on four occasions and had developed diarrhoea, passing jet-black stools.

On admission he felt very weak and thirsty. His mucous membranes were pale and his tongue moderately dry. The pulse rate was 112, and the blood pressure 115/70. There was an apical systolic murmur. The liver and spleen were not palpable. On Sept. 9 he vomited 57 oz (1.6 litre) of material which had the appearance of "coffee grounds," and he also had a large melaena. In spite of transfusions he died the same day. The cause of death was given as "haematemesis and melaena from a duodenal ulcer." Consent was not given for a necropsy.

I wish to thank Dr. A. D. Rope for allowing me to use the notes of one of his cases (Case 2), and Col. W. I. FitzGerald-Powell, late R.A.M.C., for permission to publish this report.

A. G. FREEMAN, MRCS, LRCP,
Late Captain R.A.M.C.

FORENSIC MEDICINE

Rättsmedicin (Forensic medicine) By Einar Sjövall, J.D. M.D. (Pp 182, paper cover, 11 Swedish crowns, bound, 144 crowns, in Swedish) Stockholm Wahlstrom and Widstrand 1946

The author of this book is professor emeritus at Lund University and has over thirty years experience of his specialty. He has written not a textbook but a general survey of the scope problems, and methods of forensic medicine primarily for the legal profession. Though a knowledge of anatomy, physiology, and pathology is necessary for a full understanding of the specialty, he presents it in a simple manner, and medical students who like to get a bird's-eye view of a subject before reading standard textbooks will find it invaluable.

The book is distinguished by the author's high conception of forensic medicine in the service of justice, by his concentrating on the solution of problems by scientific methods, and by his freedom from the prudery and attitude of moral superiority occasionally seen in teachers of this subject. The topics discussed include professional secrecy, determination of the fact and time of death, identification, sudden death from natural causes and after treatment by quacks, the results of various forms of violence, death from physical agents, poisoning, sexual offences, abortion, and infanticide. There are no pictorial illustrations, but their absence is compensated for by numerous case-records, which are models of brevity and relevance. The author stresses the value of full collaboration between the medical expert and the police authorities, and draws attention to the importance of post-mortem examinations, since they often result in the exoneration of suspected persons.

Considerations arising from this book are that medical students might well confine themselves to learning general principles, much of the detailed knowledge now required for examinations being left for postgraduate study, that teachers of law and forensic medicine should regularly collaborate in the teaching of both medical and law students, and that one function of full-time professors of this specialty should be scholarly criticism of the law. An English translation of the book adapted to English law would be valuable.

R WHITEHEAD

INTRODUCTIONS TO FEVERS

The Acute Infectious Fevers. An Introduction for Students and Practitioners. By Alexander Joe M.D. F.R.C.P.ed., D.P.H., D.T.M.&H. (Pp 276, 64 illustrations 18s) London J and A Churchill 1947

Infectious Diseases. With Chapters on Venereal Diseases. By A. B. Christie M.D., D.P.H. (Pp 324 12s 6d) London Faber and Faber

Each of these new books on infectious disease serves a useful purpose—the first as a reliable handbook for students and practitioners, the other as the complete textbook for the nurse.

Clearly Dr. Joe has followed in the footsteps of his predecessor, Claude Ker, for his book is essentially an account of the clinical material that he has himself observed. This makes it more interesting and avoids the modern tendency to give a 'card-index' review of a subject, which, although valuable for reference, fails to satisfy the general reader.

The clinical descriptions are good though perhaps because of the personal emphasis we may dispute some of the interpretations. We should have liked to see for example, a more detailed account from the clinician's viewpoint of the streptococcal group of diseases. The author advises the early administration of antitoxin in the treatment of scarlet fever, but should he not stress that it can have little effect upon complications caused by direct extension of the infection from the throat? The use of serum in cases of septic scarlet fever seems illogical, for here we are dealing almost entirely with local streptococcal invasiveness. Again passive immunization with scarlet fever antitoxin may be of benefit in masking the effects of the erythrogenic component of the streptococcus, but tonsillitis may continue to spread among the immunized and so keep

active the streptococcal transference until passive immunity has waned. We are also surprised to find bronchopneumonia listed as the main serious lung complication in whooping-cough. Segmental or lobar absorption collapse undoubtedly accounts for many of the so-called pneumonias and is the more dangerous because of its possible after-effects. Further, a remarkable number of the lung complications are tuberculous in origin and the older clinicians' conception of this disease as a frequent sequela of whooping-cough is still regarded as true. However, these are merely differences of emphasis. The author presents an excellent survey of the common fevers which should prove popular with students. The practitioner will find that this handy volume fulfils his clinical needs and that it is useful for rapid reference.

In Dr. Christie's book we have at last a good fevers textbook specially written for nurses. Though a nurse could scarcely be expected to know all of it for her State examination, it would be an excellent reference book for the student wishing to supplement her lectures. For the health visitor's course it is the only book of its kind dealing with all the infectious diseases that she will meet, and it includes valuable chapters on public health practice and the social aspects of fevers and venereal diseases. It is highly recommended.

NEW THEORY OF JAUNDICE

Les Icteres. Moyens d'Exploration. Symptomes. Physiologie. Pathologie. Therapeutique. By I. Pavel. Second edition (Pp 189, illustrated. No price given) Bucharest I. Pavel 1944

In this book, which in format and style is typical of the French school, Dr. Pavel, of Bucharest, gives his views, developed over 20 years of clinical observation, on the origin, classification, and treatment of jaundice. He discusses chiefly cases of jaundice due neither to organic obstruction nor to haemolysis and refers only briefly to the latter types. He thinks current theories of bilirubin formation and excretion do not satisfactorily explain the frequent lack of correlation between liver damage and jaundice and provide no simple interpretation of the results of the direct and indirect van den Bergh reaction. He would expect the "direct bilirubin" reaction to be diminished and not increased in liver cell damage if this form of the pigment is indeed a product of normal liver-cell function. He suggests that bilirubin does not pass through the liver cell but is excreted into the bile canaliculi by the Kupffer cells, which change it from the "indirect" to the "direct" form. The liver cell aids biliary flow in concentrating the bile by resorption of water and creating a relative negative pressure in the bile channels. The appearance of jaundice in cirrhosis with jaundice would depend on the relative functional integrity of the liver cells and Kupffer cells.

The author believes that the cause of jaundice not due to haemolysis or organic obstruction most commonly originates in the duodenum. Investigating these cases by intubation and radiology he concludes that they are mostly due to a functional spasm of the sphincter of Oddi or to a catarrhal inflammation involving the duodenum, biliary passages, and pancreas. The interpretation of the tests is subjective and, one might add, uncritical, so that the conclusions, which partly revive Virchow's theory, have not been widely accepted. Dr. Pavel gives interesting case histories in support of his views, illustrating in particular the supposed role of emotional and nervous factors in the production of jaundice and the beneficial results of his taken surgical intervention. Putting his theories into practice he recommends purgation and duodenal lavage to rid the body of toxic products formed in the duodenum, especially from proteins, which, with the exception of milk, are excluded from the diet in the treatment of catarrhal jaundice. If these and other measures fail, he recommends operative intervention to re-establish biliary drainage.

The author's arguments are sometimes difficult to follow, but his evidence appears insufficient to substantiate his theories. The difficulty of interpreting an empirical test like the van den Bergh reaction hardly justifies the construction of a new theory but argues rather for not attaching too much importance to the type of van den Bergh reaction. It cannot be denied that spasm of the sphincter of Oddi and catarrh of the biliary passages are possible causes of jaundice, but we cannot ignore the evidence

that so called catarrhal jaundice is a virus infection of the liver, and aspiration biopsy has shown that the jaundice is, in fact, related to liver-cell damage

PAUL FOURMAN

GOOD EARTH

Thoughts on Feeding By Lionel J. Picton, OBE (Pp 265, illustrated 12s 6d) London Faber and Faber

In much of this book the author stresses the value of foods grown with the aid of natural manures and compost. The loss of nutrients in the urine and faeces of our great urban populations is undoubtedly a major disturbance of the cycle of Nature. It is not easy to see how it can be prevented in the near future, yet any biologist must think that, like the impoverishment of our mineral and timber resources, it is one of the limiting factors of Western civilization and must sooner or later be ended. Some of the ideas which Dr Picton advances and which are associated particularly with the names of Sir Albert Howard and Lady Eve Balfour are, to say the least, highly controversial. It certainly would not be true to say of the animal creation that insects and fungi do not cause disease, or that protection by means of sprays, powders, and so on is unscientific and unsound. Surely no malariologist would subscribe to such a doctrine, and malaria is one of the most serious diseases of mankind. It is therefore difficult to believe that these "basic principles" can be true of disease in plants or that the abolition of chemical fertilizers and parasiticides would promote animal and plant health. The more widely supported view is that only a judicious combination of humus and chemicals can attain this end. In any event, a civilization whose manure is wholly organic has been a stark impossibility for many years. Evidence for these statements is given in many publications, such as David Lilienthal's book, *TVA on the Tennessee Valley* scheme or Donald Hopkins's *Chemicals, Humus and the Soil*.

Nevertheless, we entirely agree with much else that Dr Picton says. We of the younger generation sometimes forget the immense advance in knowledge of nutrition made during the professional life of men like Dr Picton. It needed the Boer War to reveal the deterioration in national vigour brought about by a diet of tea, white bread, and jam, and the 1914-18 war to start the first large scale measures to redress it. The importance of the protective foods, the vitamins, and the trace elements—discussed by Dr Picton with a wealth of historical instance and personal experience—is still too little known to the general public. Coal and agriculture are to be the two main factors in our readjustment to the post-war world, and it is therefore fitting that a group of doctors practising between the coalfields of South Lancashire and the rich grass lands of Cheshire should have signed the medical testament on which Dr Picton's book is to some extent a commentary. We wish them success in their proselytizing, advising them only to be sure to base their preaching on sound evidence.

L. J. WITTS

STUDENTS' HANDBOOK

Aids to Medical Diagnosis By G. E. Frederick Sutton, M.D. Sixth edition (Pp 308, 46 figures 6s) London Baillière, Tindall and Cox 1946

There can be few volumes which contain so much information in so small a compass as does this popular little book. The teaching is factual and sound, matters of controversy and speculation are rightly excluded, all sections have been brought up to date, and a chapter on the electroencephalogram has been added. The student will find it valuable in the medical out-patient department and afterwards. Dr Sutton is to be congratulated on writing so compactly and compendiously on elementary medical diagnosis and on avoiding the irrelevances which commonly disfigure such works.

R. BODLEY SCOTT

Dentistry: An Agency of Health Service (Geoffrey Cumberlege Oxford University Press 8s 6d), edited by M. W. Carr, DDS, contains articles by various American authors on the development of dentistry as a profession on dental education and practice and suggestions for research. Though one cannot always agree with the opinions expressed, the book is of interest and value to those who are concerned with the public health and preventive aspects of dentistry.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

War, Sadism and Pacifism By Edward Glover, M.D. (Pp 292 9s 6d) London George Allen and Unwin 1947

An approach to the problems of war and pacifism by a psychoanalyst

Diseases of the Heart and Kidney By J. C. Banerjee, M.B., M.R.C.P., and P. K. Chatterjee, M.B., M.R.C.P. (Pp 184 Rs 8) Calcutta U. N. Duhr 1947

A clinical account of cardiovascular and renal diseases, intended for medical students and general practitioners

Transactions of the American Therapeutic Society Vol XLIII 1943 (Pp 98 No price) The American Therapeutic Society 1944

Papers on various subjects, including heparin, the treatment of tuberculosis, and vitamin C in peripheral vascular failure

The British Journal Photographic Almanac (Pp 444 5s) London Henry Greenwood 1947

Contains instructions for many photographic processes and an article on medical photography

The Treatment of Impotence By Joseph Loewenstein, M.D. (Pp 48 5s) London Hamish Hamilton 1947

The author describes his conditioning apparatus and includes a number of case histories in which it was used successfully

Sick Children: Diagnosis and Treatment By Donald Paterson, M.D. F.R.C.P. 6th ed (Pp 455 16s) London Cassell 1947

This edition includes the latest views on haemorrhagic disease of the newborn and erythroblastosis foetalis, and there is new material on the sulphonamides and penicillin

The Student's Handbook of Surgical Operations By Sir Frederick Treves 8th ed revised by C. P. G. Winkley, C.B. D.Sc., F.R.C.S., F.R.S.C. (Pp 374 15s) London Cassell 1947

Fifty new illustrations have been included in this edition and new portions on the chest and heart and on neurosurgery added

An Introduction to Physical Education By Eugene W. Nixon and Frederick W. Cozens 3rd ed (Pp 251 14s) Philadelphia and London W. B. Saunders 1947

The authors describe the history, aims, and methods of physical education as well as the qualifications required for teaching it

Cu Inry's Pharmacology and Therapeutics 13th ed revised by Arthur Grollman, A.B., Ph.D., M.D., F.A.C.P., and Donald Slaughter, B.S., M.D. (Pp 868 45s) London J. and A. Churchill 1947

This edition incorporates recent advances in chemotherapy, endocrinology, and vitamin therapy

Practical Physiological Chemistry By Philip B. Hawk, Ph.D., Bernard L. Oser, Ph.D., and William H. Summerson, Ph.D. 12th ed (Pp 1,323 50s) London J. and A. Churchill 1947

New sections have been introduced on the polarograph, isotopes, sulphonamides and antibiotics, photometric analysis, and the composition of foods

Leitfaden für Zuckerkrankhe By Dr Georg R. Constam (Pp 126 12 50 Swiss francs) Basle Benno Schwabe 1947

Instruction for the diabetic, intended for the layman

Die Milzpunktion By Sven Moeschlin (Pp 205 30 Swiss francs) Basle Benno Schwabe 1947

A monograph on the technique of splenic puncture and the evidence to be obtained from it

Les Parathyroïdes Humaines Contribution à l'Étude des Hyperplasies et des Adénomes By Markus Wernli and Ch. Berdy Chamsi (Pp 144 10 Swiss francs) Basle Benno Schwabe 1947

A study of parathyroid hyperplasias and their effects

Zur Chemotherapie der Sulfone gegen Tuberkulose By O. Acklin, E. Rossi and M. Schmid (Pp 25 2 Swiss francs) Basle Benno Schwabe 1946

A monograph on sulphone chemotherapy in tuberculosis with an account of experiments on guinea pigs

Nova et Vetera

JOHN AND WILLIAM HUNTER

New Aspects of John and William Hunter By Jane M Oppenheimer I Everard Home and the Destruction of the John Hunter Manuscripts II William Hunter and his Contemporaries Foreword by Fenwick Beckman M.D. (Pp 188 25s) London William Heinemann Medical Books 1946

This charmingly written and delightfully produced little book is made up of two lesser books. In both Miss Oppenheimer has produced so many unobserved relationships of known facts that she must be treated as a historical discoverer in her own limited field—namely, that English social scene in which medical education in England took its modern shape.

The first booklet is on 'Everard Home and the Destruction of the John Hunter Manuscripts'. Home, though not a man of great mental power was intellectually restless. He was weak, worldly, and vain, but had social powers and was a competent and highly successful surgeon. His name is attached to scores of papers in the Philosophical Transactions of the Royal Society. The merit of those that have any is that they are obviously products of the *bottega* of his brother in law, John Hunter, whose assistant he was. Home would have no mention in the history of science and retain only a minor reference in the history of medicine but for one act of supreme infamy which has given him a place among the immortals. None who has looked into John Hunter's career and work will doubt that the nature and achievement of his genius are peculiarly difficult to set forth and that they still await adequate interpretation. The task has been made incomparably harder by Everard, who deliberately destroyed John's records. The damage that he did to them is greater than that done by Nazi bombs, which destroyed only Hunter's museum. Home working as a fifth column from within, did his best to filch Hunter's thoughts. He was incapable of presenting them himself, and his theft meant in effect the loss of many of them.

Miss Oppenheimer an admirable advocate well informed and skilful, charitable and understanding seeks to defend the wretched Home. Her fascinating red herrings, some of a new pattern, drawn across the slimy path of Home do not prevent us smelling the rat that dwells with the skeleton in Home's cupboard. Home has been tried in the court of history and found guilty of lying, faking, meanly robbing a dead man, and basely destroying precious scientific records. Despite his advocate's eloquent and able presentation of extenuating circumstances the appeal will we believe fail with the candid reader. He will not however, find that he lacks either entertainment or instruction in hearing the appeal for the defence. He may care to hear again one witness the devoted, self sacrificing servant of Hunter, William Clift, who had lived for six years on 7s a week to preserve Hunter's collection and to that end had freely given out of his poverty.

'Sir Everard began by telling me. Clift told the Select Committee on Medical Education, that an accident had very nearly occurred at his house that it had been nearly on fire and that the firemen insisted upon taking possession. They saw the flames coming out of the chimney. He did not wish to admit them, but they insisted. I asked him how it happened, and then he told me that it was in burning those manuscripts of Mr Hunter.'

I said to him, I hope, Sir Everard, you have not destroyed those ten volumes relating to the gallery?

He said, Yes.

And Mr Hunter's lectures?

Yes.

And then I mentioned perhaps 20 others, that I had a very perfect recollection of. I felt that all those hopes that I had entertained were entirely frustrated and destroyed. I considered that my life had been spent in the service of that collection, and I hoped to have lived to see those papers beneficially employed. When I had made inquiry respecting the principal of them, and he told me they were all gone, I said to him, 'Well, Sir Everard there is only one thing more to do.'

He said, What is that?

I said 'To burn the collection.' I knew that that week Sir Everard had received back from the printer the last proof of his second volume of *Lectures on Comparative Anatomy* and that he had used those papers very largely in the composition of that work.

So long as men condemn things that are low and mean the name of Home will be remembered.

When the final appraisal is made of John's greatness it must be largely through the six great quarto volumes of *Lectures on Comparative Anatomy* (1814-28) that Home published in his own name. We cannot allow it an extenuating circumstance that Home should insert in that work statements that he owed much to Hunter. That was so but it was common knowledge and Home had no means of concealing it. The point is that all the treasures in that great series of observations are Hunter's not Home's, and that Home had the effrontery to attach his name and portrait to them.

Miss Oppenheimer's other section, 'William Hunter and his Contemporaries', is a very different type of work. It is a subtle, readable, and informative psychological study. How came it that one so far seeing public spirited, and generous as the courtly and highly experienced William Hunter could be in social matters so small, in politics so much of a weathercock in science so jealous? The essence of Miss Oppenheimer's answer is contained in the word 'frustration'. William's nobler ambitions were never allowed to fructify. He was a very successful man in the world's eyes but not in his own. Yet time has reversed the decision of his contemporaries that paid more regard to his personal qualities than to his public spirit. Medical education at long last has been forced to take the path that he had laid down for it and for which he was prepared to sacrifice his fortune.

That their English contemporaries failed to appreciate the vision and generosity of the two great-hearted Scots brethren was a loss to England which we feel to this very day. Miss Oppenheimer discusses them wisely and well.

FINE MEDICAL LIBRARY DISPERSED

The friends of Prof F C Pybus of Newcastle, have long admired the collection of ancient medical books which he has amassed by the labour of many years, and they have learnt with mixed feelings that his library was dispersed on March 19 at Messrs Sothebys, of Bond Street—regret that it should be scattered tempered perhaps with satisfaction that an opportunity of filling gaps in other collections should have been afforded. Prof Pybus had many desirable rarities of the sixteenth and seventeenth centuries, but he by no means neglected the eighteenth and nineteenth. Only a few of the more outstanding items from the catalogue can be particularized here.

The sale began with two books by Aetius of Amida published at Venice in 1534 and Basle in 1535 respectively. Aetius's *De Corporis Humani Partium* Venice, 1552, followed after some eighteenth-century lots later on were to be found Celsus *Medicinae Libri VIII* Venice 1528. William Cowper's *Anatomy* first edition Oxford 1698. Columbus Realdus, *De Re Anatomica* Paris, 1562. two Galens, Paris, 1528 and Basle, 1538, respectively. William Harvey's *De Generatione Animalium* first edition, London 1651, the first English translation of the same work, London, 1653. three copies of his *Anatomical Exercitationes Concerning the Motion of the Heart and Blood* 1660 1673, and 1673, Hippocrates *Opera Omnia* 1526 and 1546, several of John and William Hunter's works. a first edition of Jenner's *Inquiry into Cowpox* 1798. Peter Lowe, *Art of Chyrurgery* 1654, Mercurialis 1569 and 1572. Jacobus Pacinus, *De Tenuis Humoris Febrem Faciente ante Purgationem per Artem Incrassatione* (what a title!), Venice 1558. Paulus Aegineta, Basle, 1538. *De Puerporum Morbis*—a Sebastiano Austrio, Lyons, 1549, J Y Simpson's *Notes on the Inhalation of Sulphuric Ether in the Practice of Midwifery* Edinburgh, 1847. Israel Spachius on midwifery, Strassburg 1597. three Sydenhams of 1668, 1676, and 1685, Vegetus Renatus, *Artus Veterinariae* Basle 1528. Vesalius *De Humani Corporis* Basle 1555 and three of Thomas Willis's works 1668, 1672, and 1682.

The United States Public Health Service is to carry out research on BCG vaccine (BCG was discussed in a leading article in the *Journal* July 27, 1946, p 125.) Techniques of preparation and standardization will be developed. The vaccine will not yet be commercially available in the United States. New York State is to produce and test BCG vaccine. Dr Konrad Birkhaug the Norwegian authority, has been engaged to work for the State Health Department.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY MAY 31 1947

MEASURES OF MORTALITY AND MORBIDITY

For defining the principal current problems in the fields of public health, preventive medicine, social medicine, and epidemiology—call these closely related subjects what we will—and for being in a position, as the immediate practical corollary, to take appropriate steps to cope with these problems, the first and fundamental requirement is an efficient system of recording the mortality and morbidity experience of the population. Without these vital statistics, with all their well-known imperfections and sometimes serious difficulties of interpretation, we are largely working in the dark, with no yardstick by which to measure progress (or lack of progress) and no certain indication of the weak points in the communal health upon which it would be wise to concentrate.

From the viewpoint of mortality we in Great Britain are finely served with the annual reports of the Registrars-General dating back over more than a hundred years and based upon the registrations of death. By such means, for instance, we can study, over a long or short period, the progressive saving of infant and child life, noting also, with considerably less complacency, the local and regional contrasts that still remain. Or, with an ageing population, we can consider the problems that are likely to face the new Health Service as time passes. With causes of death, fundamental though they are, we are on far more difficult ground. Fashions in nomenclature come and go, standards of diagnosis are improved, methods of certification and of tabulation change. The resultant figures are often difficult to interpret, and it would be fair to say that the vital statistics may throw up more problems than they solve. A current instance is the increasing registered mortality from cancer of the lung. Is it real, in the sense that persons to-day are more likely to die of it than were the previous generation, or is it merely an artificial rise due to improved methods of defining the primary site of the growth and thus the true cause of death? The statistics themselves will not answer the question, but they produce an important problem for thought and one worth the development of a means of inquiry. Such evidence and problems of the national mortality experience, and of its age, sex, and geographical components, the Registrar-General of England and Wales has placed before us annually in his tabulation of the mortality and fertility records (Parts I and II, Medical and Civil Tables) and in his analysis of and valuable commentary upon them (the Text volume). With the war the sequence was inevitably broken and though some of the basic tables for the war years have been issued the Text volume has lagged behind. To catch up arrears the Registrar-General has now issued a combined volume for

the years 1938 and 1939,¹ and in a further one he will cover the six years 1940 to 1945.

The present volume, although it relates to those curiously far-off years preceding the war, has much of interest in it. In particular, much space is devoted to the situation then with regard to fertility, for under the Population (Statistics) Act of 1938 the Registrar-General has been able to obtain at the birth of a child confidential information about the age of the mother, her previous fertility, and the duration of the marriage. Apart from the great importance of these details in relation to the population problem they have a bearing upon such medical questions as the association between infertility and disease and the effects of maternal age and birth order upon the stillbirth rate. This rate, for instance, was falling slowly just before the war and more rapidly during the war. Its frequency is generally at its highest among first-born children, drops to its lowest level for the second child, and then increases with the number of previous children. For children of a similar birth order it generally increases progressively with advancing age of the mother. Changes in the total crude rate, covering, as it does, mothers of all ages and births of all orders, may be due therefore not solely to environmental factors, such as better pre-natal care and better diet, but to a changing pattern in fertility—perhaps fewer births of the higher orders or fewer in older women, in whom the stillbirth risk is at its highest, or more first-order births. These new figures will allow the favourable trend of the last few years to be dissected and more clearly interpreted. Unlike Scotland, we have at present no record of the causes to which the stillbirths are attributed, a defect which it would seem worth while correcting in spite of the essential imperfections of the data.

For infants born alive some curious sex ratios in mortality are shown. In 1939, for instance, the male rate for the whole of the first year of life was 28% higher than the female rate. On the first day of life the male excess is 20%, it rises to 33% in the remainder of the first week, falls back to 20% for the second to fourth weeks, then rises steeply to 43% in the second and third months, and thereafter declines to 28, 27, and 13% in the ensuing three-month periods. Mortality of illegitimate infants was approximately twice that of legitimate infants on the first day of life and in the second and third months, but rather less in excess at other points of the year. The general trend of infant and child mortality can be illustrated by conversion of the death rates into life-table form. At the death rates of 1871–80 of every 100 boys and girls born alive 73 and 76 would have survived to their fifth birthday, before the first world war, 1910–12, the figures had risen to 83 and 85, and before the second, 1938–9, to 93 and 94. Comparable figures for survival from birth to age 15 are, approximately, 70 boys and 72 girls in 1871–80, 80 and 83 in 1910–12, 92 and 93 in 1939. In 1939 a striking new feature of early child mortality was the phenomenally low mortality from measles, scarlet fever, and bronchitis and pneumonia. In contrast to these gains, and indeed to those at most other ages, the death rates of males at ages 50–65 have shown

¹ The Registrar General's Statistical Review of England and Wales for 1938-39 (New Annual Series Nos 18 and 19) Text H.M.S.O. 4s 6d net post free

little change since 1923, a feature which is due to a large and continuing rise in the deaths assigned to degenerative heart disease. In seeking an explanation of this rise the Registrar-General suggests that it may be significant that men of this age group in 1939 were aged 25-44 in 1914-18, when many of them were subjected to abnormal stresses.

While we have, therefore, no dearth of material to study and analyse in the field of mortality, it is equally clear that stone dead, though it may have no fellow, is unlikely to be an all-sufficient guide. During the war (and since) we were constantly told that the health of the nation was never better. But in this respect mortality indices are not wholly convincing, we need information on, at least, the incidence of major and, if possible, minor illnesses, and cannot concentrate only on those that have a fatal result. Beyond, however, the notifiable diseases and some information from national health insurance records we had but few data. It was to meet this need that the Government's Social Survey organization, on behalf of the Ministry of Health, started a continuous survey of the prevalence of sickness. Using a small but randomly chosen sample of some 2,000 to 3,000 persons per month—each time in a varying set of districts—and by the home-visiting of each by trained investigators, it has endeavoured not only to construct a general picture of the incidence of illness but to accumulate sufficient data to demonstrate the nature and frequency of ailments and injuries at different ages, between the sexes, and in relation to geographical and social variables. The survey is, of course, entirely on a voluntary basis, there is neither "snooping" nor compulsion, but it is reported that out of some 81,000 people interviewed up to December last year only about 0.5% refused to take part. Some results of this work have been published from time to time in the *Monthly Bulletin of the Ministry of Health and Public Health Laboratory Service* and in the recent report of the CMO on the health of the nation in the war years, but there has so far been lacking a sufficiently detailed account of the Survey's scope and methods to allow interested workers to judge fully of its value and limitations. That lack has now been partially corrected by the preparation, by Patrick Slater, of a report on the Survey of Sickness, October, 1943, to December, 1945. It is only partially corrected, for unfortunately this report is not on sale, and a copy can be seen only by arrangement with the Director of the Social Survey.² When paper supplies are less restricted it is to be hoped that this and other reports of the Social Survey will be made available both to the public and to workers in allied fields—in other words, not only for the information of the former but also for the use and criticisms of the latter.

Apart from a description and discussion of the details of methodology the present report gives results which have not previously been published. The illness and injury rates are analysed by age groups. The former, as one would expect, tends to rise fairly steadily as age increases, but the latter shows a relatively high rate at ages 16-24, a fall to a minimum at 35-39, and then a fairly steady increase up to 55-59, with, perhaps, a fall in the final age group 60-64.

In urban areas the injury and illness rates are both higher than those in the rural areas, with rising income sickness falls, but liability to injury shows no clear change, there is apparently no association between the incidence of illness and injury and the number of persons per room. The obvious objection to these simple comparisons is that only one feature is being examined at a time. For instance, the comparison of the rates of sickness at different levels of overcrowding or for different income levels may be affected by different age constitutions in the populations at risk. Standardized rates are required, and though the author in defence says that "the intention here is merely to provide an impartial exhibition of the diversity in the data—to suggest problems rather than solutions"—it is not obvious that such crude rates can fulfil even the former aim. Other data collected in these inquiries allow an estimate to be made of the extent to which medical opinion is consulted in sickness or in injury.

The main value of this still experimental work clearly lies in its capacity to reveal periodic changes in the public health, thus linking up with and adding to the death records. But to fulfil this purpose adequately it must be published, and in future, the Report states, such figures will be included in the Quarterly Return of the Registrar General. A specimen return is included in the present report, and potential users are invited to comment and stress their needs. In addition, it may be noted, special inquiries—e.g., into the incidence of deafness—can sometimes be usefully tacked on to the routine health survey. The organization is there, and we have made a useful start towards getting one measure of the sickness rates prevailing from time to time.

THE VOLE BACILLUS

The revival of projects for active immunization against tuberculosis by means of BCG vaccine requires that the comparative merits of a vaccine containing the vole acid fast bacillus should also be considered. It is therefore useful to have an account of everything which is known about the properties of this organism, including previously unpublished information about the immediate effects of inoculating human beings with living vaccine made from it. This account is given by A. Q. Wells, the discoverer of the vole bacillus, in a recently published monograph entitled "The Murine Type of Tubercle Bacillus".¹ The decision to regard the organism as a third distinct mammalian type of *Mycobacterium tuberculosis* is clearly correct, although for the time being it is likely to retain its original, brief, and more familiar name.

Wells identified this bacillus as the cause of a widespread disease in wild voles in 1937. The most striking feature was the formation of chalky subcutaneous masses, over which the skin was liable to ulcerate, containing enormous numbers of acid-fast bacilli, lymph nodes were extensively involved, undergoing caseation, and lesions sometimes occurred in the lungs, liver, and spleen. Animals so affected were trapped in widely separated

² Survey of Sickness to be seen by arrangement with Mr L. Moss, Director Social Survey 39-41 Nottingham Place W1 (Wellbeck 8536).

¹ Med Res Cncl Sp Rep Ser No 259 1946 published March 1947

areas, including Oxfordshire, Wales, and Scotland. The further information about this disease now published includes several points of interest. It has been identified in three other species—the bank vole, the wood mouse, and the shrew. It has been shown to be an exceedingly chronic condition, an advanced stage of which has little apparent effect on the animal's activity. It is indeed so chronic that there is "no evidence that the expectation of life for a tuberculous vole is any less than for an uninfected vole." Study of the possible routes of infection has shown that cannibalism is likely to be a major factor. The contamination of water, and to a less extent mere cage contact, where food may be contaminated by an infected animal, will also produce the disease.

The vole bacillus is distinct morphologically and culturally from other types of *Myco tuberculosis*. It is indistinguishable serologically from the human and bovine types, as is here clearly shown by agglutinin absorption tests also embracing the avian type, *Myco phlei*, and *Myco smegmatis*. A tuberculin prepared from it gave reactions almost equal to those produced by standard tuberculin in guinea-pigs infected with "mammalian" tubercle bacilli (presumably human or bovine). Its pathogenicity, however, is strikingly distinct. Although a large dose intraperitoneally may cause progressive and fatal disease in the guinea pig, subcutaneous injection of anything less than the very large dose of 5 mg produces only a local lesion. That such infection, in either guinea-pigs or calves, produces a high degree of resistance to subsequent inoculation with virulent tubercle bacilli is of course the main fact to which the discovery of this organism owes its practical interest. The early observations by Wells himself, by the late Stanley Griffith, and their colleagues, strongly suggested that the degree of this resistance is greater than that produced by BCG. This work had to be abandoned early in the war, and the guinea-pigs in Wells's and Brooke's main experiment were killed only about three months after their inoculation with virulent bacilli. At this stage there seems to be no doubt that the extent of disease was much less in the vole bacillus than in the BCG group. Experimental study was not entirely abandoned during the war. K. Birkhaug² now recounts the smuggling of cultures from Oxford into Norway which enabled him to repeat the Oxford experiment, with the difference that the animals were allowed to survive indefinitely. Whereas all controls died in little over 200 days, nearly all the immunized lived for 300 to 600 days, but the difference in survival time between the vole bacillus and the BCG group was not significant. The last word has evidently yet to be said on this subject, but in any assessment of the relative merits of the two vaccines another property must be given due weight. BCG is a bovine bacillus of artificially lowered virulence and its stability from this standpoint is uncertain. Some fear the possibility of spontaneous enhancement, more likely perhaps is a greater degree of degradation with loss of immunizing efficiency. The vole bacillus, on the other hand, is naturally avirulent for other animals, and requires only to be maintained in its normal host to preserve its present characters.

The most advanced stage of Wells's work, here described for the first time, is the inoculation of human subjects with living cultures of the vole bacillus. Subcutaneous injection of a dose varying from 0.025 to 1 mg was practised in 51 subjects, most of whom developed slowly healing ulcers at the site of injection, there was no involvement of lymph nodes or sign of any other ill effects. The multiple puncture method, now considered the best method of inoculation with BCG, was employed in 69 subjects, and produced a varying number of papules which remained visible for one to three months. All these subjects, originally tuberculin-negative, acquired tuberculin sensitivity except two given the smallest dose by the latter method. This procedure is therefore safe, effective as judged by the acquisition of tuberculin sensitivity, and free from the drawback of producing an open lesion and a subsequent unsightly scar if the multiple puncture method is used. How vital a stage has thus been passed in the development of what may be a valuable method of immunization needs no emphasis.

RUTIN IN CAPILLARY FRAGILITY

It will be remembered that in 1936 Szent-Gyorgyi prepared a substance from lemons and from paprika called citrin. This was able to restore normal capillary fragility in guinea-pigs when an increased fragility had been produced experimentally. Now citrin is an impure mixture of two flavone glycosides—hesperidin and eriodictyol. When these glycosides were obtained in crystalline form they were found to be physiologically inert, and the active compound of the crude citrin, called by some Vitamin P, has never been discovered. Probably the active substance is rutin, which has a close chemical relationship to hesperidin, being a crystalline glycoside of quercetin and a derivative of flavone. Rutin is obtained from the leaves and flowers of buckwheat, tomato stems, yellow pansies, and many other flowers and leaves.

Rutin appears to be of value for different purposes, the most important of which is to prevent haemorrhage in patients with hypertension. It is also beneficial in hereditary haemorrhagic telangiectasis, or Rendu-Osler-Weber disease, of which Kushlan¹ has recently reviewed 1,000 cases in 175 families. The danger of increased capillary fragility in hypertension is suggested by the observations of Griffith and Lindauer,² who examined 265 patients. They determined the capillary fragility by Göthlin's method, which is to mark an area 6 cm diameter in each antecubital space and to note all blemishes which might be confused with petechiae, to apply a blood pressure cuff to each arm and maintain a pressure of 35 mm Hg for 15 minutes, to lower the pressure and count all petechiae, using a lens of 5 D, one hour later, to repeat, using a pressure of 50 mm. The number of petechiae appearing after 35 mm pressure is doubled, and to it is added the number appearing after the higher pressure. A normal figure is 8 or less, while 13 or more indicates increased fragility. Of the 265 hypertensive patients 218 had normal capillary fragility, while in 44 it was raised. The incidence of apoplexy in those with normal fragility was only 4%, whereas it was 25% in those with increased fragility. Similarly, retinal haemorrhages were present in 2% only of the normal group, but in 21% of those with increased fragility. These figures make it

² *Amer Rev Tuberc* 1946 53 411

¹ *Gastroenterology* 1946 7 199
² *Amer Heart J* 1944 28 758

clear that capillary fragility is important. By the use of rutin capillary fragility is restored to normal in a high proportion of patients. It is given in doses of 20 mg to 40 mg by mouth three times a day. Griffith, Couch, and Lindauer³ describe a return to normal in 8 patients out of 11 in two months.

In Kushlan's cases of haemorrhagic telangiectasis already mentioned the action of rutin is much more rapid. In a typical case with a family history of the condition, nose bleeding and skin lesions began in childhood. Gastro-intestinal haemorrhages began in the fourth decade. The most recent haemorrhage created a grave situation in spite of five blood transfusions. At this point Kushlan gave rutin, 40 mg three times daily. There was a remarkable change in twenty-four hours. Daily epistaxis and bleeding from the gums ceased for the first time since childhood, and did not recur.

Shanno⁴ has also described 35 cases of which 24 had hypertension, 13 of these had increased fragility which was restored to normal within twelve weeks. He also describes two patients with pulmonary haemorrhage of undetermined origin, their capillary fragility was abnormally great, when they were given rutin the bleeding stopped and the fragility became normal. It is worth noting that the rutin used by Shanno was prepared by the East Regional Research Laboratory of the U.S. Department of Agriculture by alcoholic percolation of buckwheat, it was not prepared by a commercial firm. Rutin has been given daily for as long as sixteen months without producing harmful effects.

PENICILLIN IN OSTEOMYELITIS

Staphylococcal infection in its more severe forms was given first claim on the exiguous supplies of penicillin available in the earliest therapeutic trials ever made. Acute osteomyelitis in children consequently figured largely in the original series of patients treated at Oxford, and their successful outcome was a large part of the foundation for the brilliant hopes which have since been fulfilled. Another early series was described in this *Journal* by I. M. Robertson⁵, it consisted of 7 patients, all of whom recovered completely except one whose treatment was not begun until thirty-one days after the onset. Except in one other case orthodox surgical measures were employed in addition to penicillin treatment. In experience which has accumulated since these early days bone lesions have been classed somewhat apart from all others in their response to chemotherapy: it has become abundantly clear that a focus of infection in dead bone cannot be dealt with by any methods short of radical surgery. At what stage of acute haematogenous osteomyelitis does the extent of bony necrosis become such that removal of the affected area will alone serve to eradicate the infection?

An encouraging answer to this question may be deduced from the experience of T. Twistington Higgins and his colleagues at the Hospital for Sick Children, Great Ormond Street, described in their paper on page 757. In this series of 31 cases of acute osteomyelitis 19 were of less than seven days' duration, the remainder two, three, and four weeks' or even more, all nevertheless responded to treatment on very conservative lines. Open operation was entirely avoided. Collections of pus were simply aspirated and replaced with penicillin solution. The great advantage of this procedure, as the authors point out, is that it eliminates the danger of secondary infection. When this occurs

it is often due to penicillin-resistant bacteria, with the consequence that chemotherapy cannot thenceforward exert its full effect. It also enables locally injected penicillin solution to be retained and thus to exert a prolonged and powerful effect in the neighbourhood of the lesion itself. The same treatment is indicated for suppurative arthritis and was employed successfully in 4 other cases described in this paper. The dosage of penicillin given intramuscularly was very modest by present-day standards, being strictly related to body weight, and based on an adult dosage of about 150,000 units per day. The only failure in this series appears to have been due to stopping intramuscular penicillin too soon: it should be continued for at least two and preferably three weeks. From the fact that in only 2 out of 19 of these cases so tested was the blood culture positive, these may be judged to have been on the whole examples of a less severe type of osteomyelitis. It is nevertheless gratifying that such excellent results were obtained by simple and conservative methods. No doubt the earlier treatment is begun the more confidently can such a result be expected, and it must be recognized as a grave mistake to wait for unequivocal radiographic evidence of a bone lesion before beginning treatment.

COMPARATIVE MORTALITY INDEX

A comparison of crude mortality rates between one period and another or between different areas at the same period is always likely to be misleading, because of differences in the sex and age constitution of the population. This difficulty can be overcome by the method of standardization. In our official statistics the census population of 1901 has been taken as the standard, but during the past forty years the proportion of the population aged 65 and over has increased to twice the corresponding figure for 1901. The fall in the birth rate and the decreased mortality in childhood are the two factors primarily responsible for a steady change in age distribution which has caused the standardized death rate to diverge more and more from the crude rate. In 1901 the crude and the standardized death rate were both 16.9 per 1,000, and they declined steadily until by 1938 the former was 11.6 and the latter 8.5. Although the standardized rate is a fictitious rate and is only useful for comparative purposes—for which reason it was designed—it does convey an impression that the death rate has fallen to a very low level, an impression which is unreal. The standardized death rate has been below 10 per 1,000 since 1932. To obtain an actual rate as low as this it would be necessary for the average length of life to be over 10 years, which is not yet the case.

The unreality of the standardized death rate has led to much discussion, and various alternatives have been suggested. Yule's "equivalent average death rate" has been used in the text of the Registrar General's *Statistical Review*. It employs the arithmetic mean of the death rate in thirteen quinquennial age groups between 0 and 65. The result is that which would be given by a standard population with the same numbers in each age group, but since it ignores ages over 65 it does not solve the present difficulty and is not a suitable substitute for the standardized death rate. A more recent census population figure might be used as the standard, as has been done in Scotland, where the 1931 census population is used, but beside breaking the continuity of the series of rates this could be only a temporary expedient. The population is so rapidly changing in age structure, and a further revision would be necessary in a decade or so.

A new method of comparing mortality, the Comparative Mortality Index, devised by the General Register Office

³ *Proc. Soc. exp. Biol. N.Y.* 1944 55 228

⁴ *Amer. J. med. Sci.* 1946 211 539

⁵ *British Medical Journal* 1944 1, 519

and introduced into the *Statistical Review* for 1941 (Part 1, Appendix) has been reviewed by Stocks¹. This index is a ratio and avoids a rate per 1,000. It differs from the usual method of standardizing in using a mean population for any two years for which a comparison is to be made and has therefore, an age and sex structure intermediate between the two years. To avoid the labour involved in comparing every pair of years separately, 1938 has been taken as the "base year," and the ratio of mortality for every other year to the mortality of 1938 has been calculated. By this means a comparison of the many hundreds of possible pairs of years can be simplified by an indirect approach. Instead of applying the death rates to a population midway between the two years the Comparative Mortality Index can be obtained by dividing one ratio related to 1938 by the other ratio, also related to 1938. The resulting ratio is not identical with that found by the direct method, but the difference is immaterial. Comparing 1941 with 1931, the direct approach gives a value of 0.884 for females, the ratio between the C.M.I.s with 1938 as a base is 1.043/1.183, which is 0.882. The C.M.I.s decline steadily but not so steeply as standardized death rates. Thus the ratio of the standardized death rate of 1891 to 1938 is 2.352, while the ratio for the C.M.I.s is 2.175.

In 1901 population was chosen as a standard because it included relatively few infants and old people, it formed a standard exceptionally favourable to low mortality, and its use yielded comparatively low standardized rates. The choice of 1938 as the base year for C.M.I.s was made because it was the last year undisturbed by war, for many causes it has the lowest rate of mortality up to that date, and it represents the best standard reached in pre-war conditions. After a new census it may be convenient to change to the census year as base.

RADIO-ACTIVITY IN CANCER DIAGNOSIS

The possibility of using radio-active forms of chemical elements to indicate abnormalities in the local circulation or in the absorption of the element concerned has been recognized for a number of years. Marinelli and Goldschmidt, for example, drew attention² to one case of melanoma and two cases of mycosis fungoides in which the selective absorption of radio-phosphorus was demonstrated. Cancer cells absorb a relatively large amount of newly ingested or injected phosphorus, and this fact has been related to growth requirements. Low-Beer, Glenn Bell, McCorkle, and Stone now report³ from the University of California Hospital 25 cases of actual or suspected carcinoma of the breast in which the intravenous administration of a small dose of radio active phosphate, followed by external measurement of radio-activity with a bell-jar type of Geiger-Muller counter at intervals of two, four, six, and twenty-four hours after injection, was used to give a diagnostic indication of the nature of the tumour. Of these 25 cases, 5 are described as "obviously" malignant on clinical examination, and a further 11 were proved by post-operative microscopical examination to be malignant. In all these cases the external "count" obtained was not less than 25% greater than that obtained with the counter above either the other breast or other normal tissues. In the remaining 9 cases, in which the excess (if any) was less than 25%, 8 tumours proved to be benign, and the last was a mucoid carcinoma with relatively few cells. It would

appear, therefore, that in the particular series of cases described an effective diagnostic indication was obtained. One very serious limitation must, however, be noted. Because the "radiation" from radio-phosphorus is entirely of the "beta" type—that is, consists of electrons—tissue absorption is relatively rapid. The method, accordingly, must be limited to tumours which are reasonably near the surface of the body. Moreover, the question naturally arises whether the admittedly arbitrary 25% criterion will prove satisfactory, in view of the obvious connexion between the depth of the tumour and the strength of the surface radio-activity. The authors themselves suggest that their test should not alone be accepted as an adequate indication for or against operation until a larger series of cases has been investigated. The main immediate interest of their findings is as an illustration of the type of progress which may be expected as radio-active isotopes become more widely available.

CELLOPHANE WRAPPING FOR ANEURYSMS

The surgical treatment of aortic aneurysms is still an open field, and no really satisfactory method of relief has been evolved in spite of many ingenious efforts. Wiring had a phase of popularity and is still occasionally used. Colt's umbrellae was a great improvement on coiled wire and still remains perhaps the best method, but shares the disadvantage of the other wiring methods that it is limited in its use to the saccular type of aneurysm, which is much less common than the fusiform type. Babcock¹ advised anastomosis of the common carotid artery and the internal jugular vein in an attempt to lower the pressure in the aorta, but his method has never found favour. Various methods have also been suggested and used to produce external compression of the vessel wall or to promote fibrosis and contraction of the lumen. Many of these are too traumatic and dangerous, but the use of a cellophane wrapping for this purpose seems kinder and promises better results.

Poppe and De Oliveira² point out that cellophane has been used both to produce fibrous tissue reaction and also to prevent a fibroblastic response. In this last connexion for instance, it has been successfully used in neurosurgery. This apparent paradox is explained by their investigations into the response to different varieties of cellophane which they placed around the abdominal aorta of dogs. Some varieties were almost inert, but polythene cellophane was found to produce a marked fibrous reaction so that the wall of the aorta after two and a half months was thickened to six times its normal size and its lumen was reduced to about one-third of the normal diameter.

They report the use of polythene cellophane wrapping in four cases of aneurysm of the thoracic aorta. In three of the cases insufficient time had elapsed to provide any conclusions, but in the fourth case the patient, up to the time of reporting, three months after the operation, had been completely relieved of the severe pain of which he had been complaining. They have also used a polythene film successfully for the ligation of a recanalized ductus arteriosus in a case of subacute bacterial endocarditis in which ordinary dissection and ligation would have been impossibly dangerous.

Their account of cellophane wrapping is in the nature of a preliminary report, but it seems to offer a successful method of gradual fibrosis and obliteration of aneurysms and large vessels. Accounts of further experiences will be awaited with interest.

HUMAN WATER REQUIREMENTS

An interesting paper by Dr Kenneth Mellanby entitled *Human Water Requirements* was read at a recent meeting of the Nutrition Panel of the Society of Chemical Industry. Dr Mellanby began by pointing out that the earliest forms of life existed in the sea, being bathed in a salt solution. There was some evidence that the composition of sea water was different then from what it was to day, and salt concentration in protoplasm seemed to indicate this. Thus primitive organisms were able to get rid of their waste nitrogen in the form of ammonia, which rapidly diffused in the surrounding water. When organisms evolved to a terrestrial existence they were at once in a position in which desiccation took place and they developed a more or less watertight covering and got rid of their waste nitrogen in a form less toxic than ammonia. The insect had its watertight cuticle and the bird its feathers, which cut down moisture loss from the skin surface, and both had a nitrogen end product in the form of relatively insoluble purines which required little water. Man had not evolved a watertight body surface and he excreted his nitrogen in the relatively non toxic form of urea, which required a certain amount of water.

Water Content of Man

Dr Mellanby gave the following figures for the water content of an average (70 kg) man

	Percentage of Body Weight	Litres
Intracellular (actual protoplasm of cells)	40-50	35
Extracellular { Tissue fluid	12-15	11
{ Plasma	4-5	3
		49

It was usually found that the production of 'metabolic' water and the loss of water by evaporation in the lungs ran parallel. The individual at rest lost little from the lungs and produced little 'metabolic' water. The amount of water required to prevent loss of body weight under experimental conditions was known, but whether this was sufficient for optimum health was another question. Loss of water from lungs and skin and by faeces could not be greatly modified. Experiments indicated that unless a person had a total water intake from drink and food of over 1 litre a day desiccation would take place, becoming progressively worse and eventually ending in death. In some MRC experiments during the war volunteers went from Tuesday evening to Saturday morning with no water and with a dry diet. With no fluid intake the urine output was 0.5 litre a day. As the experiment proceeded the salt content in the urine fell to 1 g per day. Abnormalities began to show themselves on the third day of the experiment. As for sensation thirst was not so evident as might have been expected, irritability and a disinclination for food were shown. The giving of 4 oz (114 ml) of water a day had no noticeable effect on urine output, it was more tantalizing than anything else. A little more effect was apparent with 8 oz (227 ml), which gave a rinse-out, but not until 1 litre was given was any real effect obtained. With no water intake desiccation depended on loss of weight. The results of German experiments in concentration camps showed that death took place usually after a fortnight but these had to be taken with reserve, for the subjects were not co-operative. For example they were found licking the swabs after the floor had been cleaned. In temperate climates death would probably take place in ten days if no water were drunk.

Camel and Desert Mouse

The amount of water lost from the lungs varied with the temperature and humidity of the air. Sweat production in a body at rest under temperate conditions was 20 ml an hour, with exercise in hot dry air it might amount theoretically to 2100 ml a day. At temperatures of over 97°F (36.1°C) death was more likely to result from heat stroke than from desiccation. It had been suggested that under conditions of desiccation it was better to eat fat because of the amount

of metabolic water which this produced. The camel stored fat in its hump and the desert mouse in its tail. But it was necessary to consider also the amount of oxygen required to oxidize fats and carbohydrates respectively. To breathe the additional oxygen required for oxidation of fats involved more water loss from the lungs, and this loss would outweigh the extra 'metabolic' water produced by oxidizing fats. The reason why desert animals stored fat was because it was the only food they could store conveniently. Dr Mellanby concluded that man must have a water intake of 500 ml over his water output in order to excrete and therefore to get rid of his harmful waste metabolites.

THE PUBLIC HEALTH

ANNUAL REPORT FOR 1945

Sir Wilson Jameson's report on the work of the medical department of the Ministry of Health during 1945 was published last week.¹ For the first time the Chief Medical Officer's report is combined with a report dealing with the more administrative and less strictly medical work of the Ministry of Health. There is much to be said for this combining of two reports which have previously appeared separately, but there is the difficulty that all vital and health statistics cover the calendar year whereas administrative figures must be related to the financial year.

An interesting feature of this report is a note on the Comparative Mortality Index (C.M.I.) Dr Stocks's work on the C.M.I., which now takes the place of the standardized death rate in the reports of the Registrar General, is the subject of an annotation in this issue at p 772.

Vital Statistics

The birth rate, which had reached 17.7 per thousand living in 1944, the highest rate since 1926, declined to 15.9 live births, which reached the low total of 580,000 in 1933, increasing to 621,000 in 1938, and to a peak of 751,000 in 1944 declined to a total for 1945 of 679,937.

The death rate was 11.4 as against 11.6 in 1944 and the civilian death rate which included violent deaths of civilians due to the operations of war, was 12.6 per thousand compared with an average rate of 12.7 for the three preceding years. The principal causes of death were much the same as in previous years. Diseases of the heart and circulatory system an old age took first place—33.1%, followed by cancer (15.2%), bronchitis, pneumonia, etc (11.4%), and vascular intracranial lesions (10.7%). These figures show again a slight increase in the proportions and numbers of deaths due to diseases most prevalent in old age. This reflects the fact that persons over 65 in 1945 comprised 10% of the population as compared with 9% in 1939.

Infant mortality was 46.0 per thousand related live births a rate slightly above the 45.4 of 1944 but well below that of any preceding year. Stillbirths comprised 28 per thousand of all births in 1945—the same proportion as that for 1944.

Comparing the corrected notifications with those for 1944 the incidence of scarlet fever decreased by one-fifth. The same applied to diphtheria, and whooping cough among children age 1-5 declined by 30%. There were more than three times as many cases of measles at ages under 5 and a fourfold increase in acute poliomyelitis among infants under one year. Dysentery notifications increased by 28% and cerebrospinal fever notifications declined by 9%.

General Epidemiology

Deaths due to influenza (2,686) were the lowest recorded for thirty years. Deaths due to diphtheria (722) were less than one quarter of those in 1938. By the end of 1945 it was estimated that 58% of the children in England and Wales had been immunized a figure said to correspond with that reached in the USA in 1936. There were 40,000 more cases of measles than in any previous year since notification began in 1940. There were, however, only 729 deaths among the

¹ Report of the Ministry of Health for the Year Ended 31st March 1946, including the Report of the Chief Medical Officer on the State of the Public Health for the year ended 31st December 1945. London: H.M.S.O. 35 (1)

46,796 notifications, giving the extraordinarily low fatality rate of 0.16%. The average fatality rate for measles used to be reckoned at 4%.

The 62,691 cases of whooping-cough had a fatality rate of 0.09%. The year saw a continuance of the relative freedom from typhoid fever (301 cases with 47 deaths), but there was a gain in the notifications of dysentery (16,278). *Sh. sonnei* was the cause of 87% of cases and the remainder were due to eight or nine types of *Sh. flexneri*. There were 12 cases of amoebic dysentery, all from overseas.

Some 434 outbreaks of food poisoning were investigated and 189 of them were apparently due to salmonella infection. The danger of consuming duck eggs not sterilized by thorough cooking was again apparent. Attention was drawn to this point in a recent leading article in the *Journal* (April 5, p. 456). In other outbreaks dried egg, meat pies, brawn, pressed beef, ice cream, and raw milk were responsible for conveying a variety of organisms.

During the year there were 515 imported and 7 indigenous cases of malaria. All the latter were benign tertian cases and the insect vector was *A. maculipennis*.

The downward trend of tuberculosis mortality has been resumed after a rise during the middle years of the war. Eighteen mass radiography units operating during the year examined some 800,000 people. Between 3 and 4 per thousand were shown to have active pulmonary tuberculosis previously unsuspected.

The incidence of early syphilis and gonorrhoea increased appreciably. In both diseases the increase was more marked in males. Thus in early syphilis the percentage increases in males and females were 18.9 and 12.0, the corresponding figures for gonorrhoea were 32.4 and 14.3. Congenital syphilis in infants under one year decreased from 345 in 1944 to 326. The number of persons attending clinics for examination and found not to be suffering from venereal disease was 84,954. The total of cases of V.D. dealt with for the first time at any centre was 50,143 as against 43,849 in 1944.

Maternity and Child Welfare

Despite the high pressure on available beds, the shortage of nursing and other staff, and difficult conditions generally, the maternal mortality rate continued to decline and reached the lowest level ever recorded—180 per thousand total births, compared with 192 in 1944. If deaths following abortions are excluded the rate was 147 per thousand total births. In addition that portion of the rate (0.24 compared with 0.28 in 1944) attributable to deaths from infection during childbirth and the puerperium was the lowest ever recorded.

What used to be called "the uptake" now appears as "the acceptance-rate" of vitamin supplements for expectant mothers and children. In the country as a whole only 25% of the cod-liver oil available was used by the mothers, and approximately 42% of the orange juice.

Food and Nutrition

Surveys of the clinical state of nutrition of various groups of the population continued during the year and "no definite evidence of existing deficiency disease was observed in any person." Vitamin feeding tests in Stoke on Trent and Salford were completed and like similar tests conducted previously, show that "in school children and in adults with diets of average wartime quality, the addition of supplements of vitamin A, B₁, nicotinic acid, riboflavin, ascorbic acid, or calciferol is not needed."

Hospital Surveys

Of special interest in this report is the review of the ten hospital surveys of 1945.

The many defects of our hospital system were not fully appreciated before the war. The surveys reveal a serious deficiency in beds (not numerically stated in all the reports, but estimated by the writer of the Nuffield Trust publication at not less than 40%) and the obsolescence of a high proportion of the existing hospital buildings. Many of these are crowded on inadequate and noisy sites in the centre of towns with poor accommodation for nursing and domestic staffs, and little or no room for expansion. Such structural defects must wait until much of the still more urgent need to build houses has been met.

The shortage and maldistribution of specialists is a second principal defect, which needs time, care, and keen foresight to rectify. Akin to this is the need for more special centres, which have proved so invaluable in the Emergency Medical Services.

Attention is also drawn to "the reproach of masses of undiagnosed and untreated cases of chronic type which litter our public assistance institutions."

Other sections of the report are concerned with rehabilitation, hospital planning and construction, and hospital catering. Medical man power is discussed at some length and there are separate sections on the Insurance Regional Medical Service, the dental services, and the nursing services. The serious shortage of nursing and domestic staff continued to react unfavourably on the efficiency of almost all classes of hospitals.

HEALTH COMMITTEES

Need for Co-ordination

The Minister of Health has again emphasized the need for the close and continued co-ordination of the local health authorities' services, under Part III of the National Health Service Act, 1946, with the general medical services and with the hospital and specialist services. A recent circular (94/47 of May 22) states: "Such co-ordination cannot be achieved unless the health committee includes proper representation of the medical profession in the area, and the appropriate body to consult for this purpose is the local medical committee referred to in section 32 of the Act." Pending the election and recognition of new local medical committees, the Minister hopes that local authorities will consult existing medical committees which he has already recognized for the purpose of medical appointments to local executive councils. Regulations relating to these executive councils were put forward recently (*Journal* May 24, p. 731).

Some local authorities have not yet constituted a health committee in accordance with the provisions of Part II of the Fourth Schedule to the Act. The circular reiterates that all matters relating to the discharge of the functions of local health authorities must be referred to the health committee and such committees must be properly constituted before effective progress can be made. The setting up of a health committee should not be deferred until executive councils and hospital management committees are in being and able to suggest representatives who can be co-opted. These additions to the initial membership of the health committee can be made at any time. In those areas where an *ad hoc* committee has been working out plans, it would be in order for the local health authority to appoint the members of this committee to be the health committee for the time being. Modifications of membership, if thought desirable, could then be made later.

GIFT FROM THE AMERICAN COLLEGE OF SURGEONS

The President of the American College of Surgeons Dr. Irvin Abell, has sent Sir Alfred Webb Johnson a cheque bringing the total contribution of that College to the restoration of the English College to over £10,000, and a brochure recording the names and addresses of the Fellows of the American College who have contributed to this memorable gift is being prepared. It may be recalled that the Great Mace of the American College was given by the consulting surgeons of the British Army in memory of mutual work and good fellowship in the war of 1914-18.

In the course of his letter to Sir Alfred Webb-Johnson, Dr. Abell writes: "From its founding in 1913 the American College of Surgeons has been benefited by its cordial relations with the Royal College of Surgeons of England, after which it was in many respects patterned. Sir Rickman Godlee, a nephew of Lord Lister, was president of the English College in 1913, and he personally represented his organization at the inaugural convocation of the American College of Surgeons, presented an official message of greeting, good wishes and hope, and was received into Honorary Fellowship in the newborn College. Since that eventful occasion many mutual interests have

strengthened the bonds between the two organizations and their individual members

The American College will make a presentation of a desk and lectern for the lecture theatre of the English College during the Congress of the International Society of Surgery to be held in London in September of this year

THE OLD PEOPLE

Mr B Seeborn Rowntree, chairman of the Nuffield Foundation Committee of Inquiry into the Problems of Ageing and the Care of Old People, addressed the British Federation of Social Workers in London the other day. Mr Rowntree told his audience that there are five and a half million old people (that is, people of pensionable age—men over 65 and women over 60). They represent 12.5% of the population, and in fifty years time it is estimated that they may represent 19%. Of these old people at least 95% live independently in private homes, only 63,000 live in institutions controlled by local authorities—mostly, of course, though not entirely, public assistance institutions—and an unknown number live in homes run by voluntary agencies. The problem concerns the 95% who live in private homes, alone, or with their families or with strangers. The Nuffield Committee has made a survey in certain sample towns—Wolverhampton, Oldham, two London boroughs (St Pancras and Wandsworth), and the Rhondda Valley. An earlier social survey of York, of wider scope, has also added to the information.

On the whole the housing of old people is not worse than that of other people of their social class, but a good many are badly housed. In Wolverhampton, for example, in the homes of the old people which were surveyed, the closets were out of doors in one third of the cases, a thing which may mean no particular hardship in the case of the young and vigorous, but is a very real hardship for the old and infirm, especially in the winter months. In Wolverhampton, Oldham, and York nearly 8% of the men and 15% of the women live alone, and in the two London boroughs 18% of the men and 29% of the women. In the Rhondda Valley there is a much stronger family feeling, and the number of old people who live alone is very small.

In mentioning the special needs of old people Mr Rowntree placed first a greatly increased provision of nursing care. In the Rhondda Valley there is one district nurse for a population of 30,000. Another great need is the institution of clubs to mitigate the loneliness of old people, especially the old men. No district in the country ought to be without its old people's club. Finally he emphasized the need for communal homes to accommodate some such number as 30 or 35 old people. The greatest evil of old age is not infirmity but loneliness. A special committee of the British Medical Association is considering the care and treatment of the elderly and infirm and its report will no doubt include this aspect as well as others.

SOCIAL MEDICINE AT OXFORD

The Institute of Social Medicine at Oxford has issued its second annual report. The staff of the Institute now numbers 17, under the directorship of Prof John A Ryle. The principal departments are the clinical and radiographic sections and the section of vital statistics. A child health survey is continuing one aspect of it is a study of congenital defects and, more particularly, cardiac murmurs recorded during the first year of life. The radiographic anatomy of the infant heart in general is being studied. Progress has also been made in the analysis of records of the growth and maturation of bone. Among the findings observed is the fact that in the first year of life the growth in the length of the bones is equal in the two sexes, but growth in width is much greater in the male. Maturation in the female is in advance of that in the male. Furthermore, it has been shown that there is in general some correlation between growth in one part of the body and growth in another, but the correlations between measurements in different parts of the same region are no closer than between those in different

regions of the body. It has been possible to draw a clear distinction between local and general factors influencing bone growth and maturation.

Another activity has been a close study of the many variations in the radiographic anatomy of the child's chest in the first year of life. About 3% of healthy children have been found to show a large mass projecting into one or both lung fields. Its nature has not yet been determined with certainty, but it probably represents the thymus gland. An analysis has been made of the spines of cretins with particular reference to the wedge deformities of the vertebrae at the dorso-lumbar junction. These deformities have also been noted in several other conditions, showing that they are not specifically related to cretinism, and are almost certainly the result of either weak musculature or structural weakness in bone. The primary cause of the deformity seems to be the flexed intrauterine position. A study of fifty consecutive cases of newborn babies revealed that similar but less marked changes might be present in normal children at birth and more recently a series of examinations of foetal spines has shown that the same deformity may be observed as early as the sixteenth week.

Other investigations concern peptic ulcer in industry, fluorine hazards, goitre, and iodine prophylaxis, and the stillbirth rate in relation to social and nutritional factors.

Preparations and Appliances

OPERATING MICROSCOPE

Mr A BROWNIE SMITH, Assistant Surgeon, Ear, Nose, and Throat Department, Royal Infirmary, Edinburgh, writes: At the present time there is a demand by aural surgeons for a microscope of long working distance for use in the surgery of the labyrinth. Details of a microscope which can be purchased now may be of interest. The instrument is a Beck "Binomax" binocular microscope to which some alterations have been made. Two new small objective lenses of 13 dioptres have been fitted in place of the original lenses, the standard illuminating attachment has been used but altered to an angle

of 90 degrees and the light reflected by means of a small mirror placed at an angle of 45 degrees between the objectives. By these modifications the working distance has been increased from 4 to 9 inches (10 to 22 cm), and the position of the mirror has enabled good illumination to be obtained even in the depths of a narrow cavity such as the external auditory meatus. The alteration of the working distance has necessitated diminished convergence of the objective lenses and, in this type of instrument, has been carried out by the insertion of small wedges in the body of the microscope. The modifications carried out give a binocular microscope with a working distance of 9 inches, a magnification of 8 with the low power eye-pieces, and a field 1 inch (2.5 cm) in diameter. There is good depth of focus and the illumination provided by a 12-volt lamp is sufficient for most purposes. The stand is fitted with two ball-and-socket joints and can easily be clamped in position on the operating table. A small sterilizable rod can be fitted to the milled knob for focusing purposes. I have now used the microscope for six months with various modifications of the light and lenses, and find the instrument described perfectly satisfactory.

The "Binomax" microscope and stand is made by R. and J. Beck, Ltd., London, and the alterations were carried out by G. Hutchison and Sons, of Edinburgh.

Reports of Societies

HYPERTENSION

At a joint meeting of the Liverpool Medical Institution and the Manchester Medical Society held in Manchester on March 5, with Prof D DOUGAL in the chair, there was a discussion on hypertension.

Dr E T BAKER-BATES said that despite the fact that hypertension had been recognized for a century our knowledge of this leading cause of death was far from satisfactory. Hypertension could be produced experimentally by procedures that induced renal ischaemia. The significant conclusion was that hypertension could *per se* produce those vascular changes in the kidney and other organs formerly believed to be of inflammatory origin (Bright's disease). A vicious circle thus became established. On rare occasions this hypothesis had been confirmed in man by observing the relief of hypertension following removal of a diseased kidney. It now appeared that hypertension resulted from sustained arteriolar constriction brought about by a chemical agent (renin) liberated from ischaemic renal tissue.

The clinician must always satisfy himself that the patient's symptoms were due to a raised blood pressure. Neglect of this principle had caused much unnecessary invalidism. Treatment remained unsatisfactory. In the majority of cases guidance of the patient to ensure a reasonable attitude towards the condition was all that was possible or necessary. Excessive zeal was undesirable and often induced an anxiety state.

In recent studies, carried out independently in America and England, 33 preparations reputed to be capable of lowering the blood pressure did not produce significant reduction in a single case. Efforts should be made to keep the blood pressure as low as possible by restriction of activities, without making the patient an invalid. Sedatives, such as bromides or barbiturates, were indicated when there were nervousness, headaches, worry, or restlessness but treatment by prolonged rest in bed, purgation, venesection, diet, baths and diathermy was of negligible value. An artificial reduction in the blood pressure often made the patient feel worse. Finally, in no other chronic and progressive malady were common sense and insight into the weaknesses and fears of human nature more essential.

Limitations of Surgery

Mr R EDWARDS considered that, since the fundamental cause of essential hypertension was still quite unknown, any direct surgical attack upon the disease was not practicable at the moment, except in two instances: paroxysmal hypertension due to an adrenaline-secreting tumour, and rare cases of unilateral renal disease. There were two factors maintaining the hypertensive state: spasm in the first place and later sclerosis. If spasm could be controlled the sclerosis might be delayed. Vascular spasm could be relieved by division of the sympathetic nervous system. Division of the splanchnic nerves produced an extensive area of vasodilatation. This area could be increased by division also of the lower part of the dorsal sympathetic chain and the upper part of the lumbar sympathetic chain. This was the method Smithwick suggested. Adson, Craig, and Peet were content with a more limited operation.

The degree of spasm was best studied by the administration of thiopentone until a deep narcosis was produced, the blood pressure being recorded as each 1 ml was administered. Full renal investigation was important. If considerable renal dysfunction was found it was unlikely that sympathectomy would benefit the patient and sympathectomy was also of little value if cerebral damage was present. A history of coronary occlusion or anginal attacks did not contraindicate operation. Sympathectomy should not be performed in patients with a systolic pressure under 200 mm or a diastolic pressure of under 100 mm Hg but this opinion might be changed in view of the considerable success obtained in America with patients showing a lower blood pressure.

The operation was done on each side with an interval of two to three weeks between the operations. The anaesthetic used was of little moment so long as controlled respiration was main-

tained, since the pleura might be entered at any time. The first 10 of his own 35 cases were treated by subdiaphragmatic splanchnicectomy, but severe and intractable post-operative vomiting led to its discontinuance. These were cases of advanced malignant hypertension in young people and the operations were performed some four years ago, all these patients were probably dead.

In the remaining 25 operations he resected the tenth and eleventh ribs posteriorly and removed a long section of the great splanchnic nerve and the sympathetic chain from the seventh dorsal ganglion down to the twelfth. An anterior transpleural approach suggested by Prof Boyd had been utilized lately and this was an improvement on the posterior method. Delayed results were obtained in 16 cases, the remainder were too recent for assessment. There was a good immediate fall in blood pressure with a gradual rise in the succeeding months, but usually not to the original level. In a small number of cases the blood pressure had remained well down. In nearly all cases headache had been permanently relieved. The operation was not a cure for hypertension but was of considerable therapeutic value in selected cases.

Familial Factors

Prof ROBERT PLATT disagreed with some of the points made by the previous speakers. In essential hypertension psychological causes and food and drink played no part in aetiology. So-called menopausal hypertension was not due to the menopause but was discovered at that time because menopausal symptoms led to the blood pressure being taken. In these cases the hypertension did not diminish later on. The most important factor in essential hypertension was familial. More than 90% of cases in which the data were obtainable had a history of hypertension in one or both parents—it was a Mendelian dominant. In secondary hypertension the familial pattern was entirely different.

He considered that malignant and benign hypertension were the same disease and had the same hereditary background. Cases of so-called malignant hypertension in young persons were nearly always secondary to urological disease. In assessing the value of surgical treatment he said that unless the diastolic pressure was reduced to below 110 mm the prognosis was probably unaltered. The headaches could be relieved by medical treatment.

Prof GEOFFREY JEFFERSON said that in his patients the blood pressure did not fall very much afterwards (the diastolic pressure very rarely going below 110 mm) and in nearly all cases the blood pressure rose again later. Of 12 of his recent cases only two did reasonably well. One a child whose blood pressure fell from 180/120 mm to 120/80 mm after two years was still very unwell. The second was a young woman whose vision returned, with a blood pressure of 155/110 mm two years later. He doubted whether these poor results justified the extensive surgical procedure necessary.

Prof A M BOYD referred to his experience with Adson's operation. This gave some symptomatic relief but there was persistence of the hyperpnea after six months. He had been using the transpleural approach, the double operation being very extensive. He thought that cyclopropane was the best anaesthetic to use, and said that after this operation it was necessary to remove the pleural effusions once or twice.

Prof C WELLS referred to his few cases done recently. He felt that sympathectomy was not the complete answer since it did not cure hypertension, but he thought that it might relieve the patient of some of his symptoms and so make life more bearable for a few months.

The Danish Medical Society has organized a comprehensive scheme of research with regard to penicillin, and in *Nordisk Medicin* for March 21 many pages (716-738) are devoted to some of the most recent Danish experiences in this field. Dr N B KRARUP points out here that continuous intravenous and intramuscular injections of penicillin have not found great favour in Denmark, where the procedure usually preferred is the intramuscular injection every third hour. The treatment of 21 cases of diphtheria with penicillin was not very encouraging, but the results in cases of scarlet fever at the Blegdam Fever Hospital have been remarkably good.

Correspondence

Physical Therapy of Mental Disorder

SIR—Dr D W Winnicott's onslaught (May 17, p 688) on electric convulsion treatment and those who practise it appears to me to contain more fallacies than most psychiatric literature, and that is saying a good deal. What he says boils down to this: that he doesn't like ECT because it is empirical. The empiricism I admit frankly, but I call his objection prejudice. When he starts to 'condense' the vague and woolly sentimentality of his first two columns, he summarizes his objections as follows: (1) 'I would not have it done to myself.' This amounts merely to an admission of prejudice. (2) It draws to psychiatry the wrong kind of doctors. This comes to exactly the same thing, besides being arrant nonsense anyhow. (3) It undermines the public's justification for relying on doctors to keep their scientific heads. So far as this sentence has any meaning it is just as devoid of foundation as (2), of which it is merely a repetition. (4) This form of therapy done here in England leads to mass treatments by the same methods all over the world. This is an indictment of the whole medical profession outside England for which I see no justification and in which I perceive no truth. (5) 'Physical methods of treatment represent a tendency away from scientific psychology.' This is merely a reaffirmation of prejudice, not a fresh argument at all.

Now, Sir, I have no pretensions to being a psychologist. I took on psychiatric work for six years during the war as a means of putting such medical experience as I possess at the service of the country during the national emergency. As luck would have it I did a lot of ECT treatment—about 9,000+ treatments of about 300 patients. I don't think I ever saw a cure of a genuine case of schizophrenia, but I did see a number of cases of marked improvement, mostly temporary. I am quite certain that it either caused, or at least greatly accelerated recovery in nearly all my cases of puerperal insanity. I am equally certain that it really cured a small proportion of cases of melancholia and that this cure was apparently permanent.

I want to put to Dr Winnicott a case of mine which was by no means an isolated one, but perhaps more inveterate than most others. This was a schizophrenic woman in the thirties who when not under treatment, was foul and degraded in all her habits, passing urine and faeces into her clothing or her bed. She was destructive of the hospital property, and violently hostile to nursing staff whom she would often wantonly attack. She was quite unemployable in any way, very difficult to feed, and miserably emaciated. She had been like this for some years when I began to give her ECT. After a course of this she became amenable to ward routine, clean and tidy in her habits, capable of needlework, and gained weight because she consented to eat. After a few weeks' cessation of treatment she would gradually slide back into her former state from which she was rescued by a further course of ECT. This sequence of improvement and relapse went on for over two years, and for all I know may be going on still. If Dr Winnicott or any other psychiatrist maintains that ECT was not justified by its results in this and many similar cases which I saw, merely because the rationale of its action cannot be explained on any scientific hypothesis so much the worse for the insane and for the psychiatrists. I hold no brief for ECT, and I deplore the exaggerations about it which immature psychiatrists have published, but at least I am sure that until something better can be devised it ought to be recognized as a valuable weapon in the treatment of (carefully selected cases of) insanity.—I am etc

Tunbridge Wells

HENRY ROBINSON

SIR—I should like to answer Dr D W Winnicott's attack on physical methods of treatment in psychiatry (May 17, p 688) with the following observations.

1 Dr Winnicott admits that he has a personal prejudice against physical therapy, surely prejudice, personal or otherwise should have no place in the mind of a scientifically trained man.

2 He makes two grossly inaccurate statements—namely, 'Convulsion therapy is purely empirical. No one has the slightest idea how it works, when it does work.' There is an increasing mass of evidence, as a result of biochemical investigations of brain chemistry and its abnormalities in the diseases under consideration, that they are organic brain disorders in which the underlying lesion is a disturbance of the oxygen-glucose metabolism of the brain tissues. In this connexion I would refer Dr Winnicott to my article on the shock therapies and their mechanism (*J ment Sci*, 1944, 90, 550).

3 Dr Winnicott completely ignores the fact that all the great therapeutic advances of the last fifty years have been the discovery of specific physical and pharmacological agents—e.g., insulin, the sulphonamides, penicillin, and so on.

4 His criticisms are entirely destructive, and he does not offer any satisfactory alternatives to the treatments which he so sweepingly condemns.

5 His remarks regarding 'magic' and 'magical treatments' are surely misplaced. The earliest forms of 'magical treatment' employed by primitive man before medicine became a science consisted of psychotherapy in the form of suggestion and persuasion. They are depicted in the paintings of Stone Age man, and are used by the tribal medicine man among savage peoples to day, differing in few essentials from the methods of some present day advocates of psychotherapy.

6 He completely ignores the undoubtedly striking results obtained by modern physical treatments in the major mental disorders, all of which are completely refractory to psychotherapeutic methods. Would Dr Winnicott, in accordance with his theories, advocate that patients with general paresis should be treated by psychoanalysis rather than by malarial and penicillin therapy?

Finally, as one who has worked for a number of years in modern mental hospitals, I can assure Dr Winnicott that it is not physical treatments but the working conditions in these institutions which deter the right type of doctors from taking up this line of work as a career—I am, etc,

London SE 6

G TAYLEUR STOCKINGS

SIR—I was most impressed by the article on the above subject by Dr Winnicott (May 17, p 688), whose feeling towards these forms of therapy I share. My own experience is small, being confined practically to ECT in the treatment of venereophobia, but his article encourages me to give it what it is worth.

The venereophobe, it must be borne in mind, is almost invariably a man of high ethical standards—a decent, respectable, and respected citizen—who, when at the end of his tether, browned off, homesick, depressed by what he had already gone through, and viewing the immediate future with complete despair, got drunk and sought comfort and oblivion in the arms of the local Circe. This is followed by overwhelming remorse and the conviction that he has become infected. Clinical examination and reassurance by specialists, the oculodemonstration of negative blood-test results, cannot shake his conviction. He comes to psychiatric treatment depressed, obsessed, and more often latently suicidal than is comfortable for his medical officers. He has ruined his life, blotted his copy book, blasted his domestic bliss, and there is no health in him.

Under my hands psychiatric interviews, narco analysis, occupational and diversional therapy met with such total and invariable failure that even I was impressed. Group therapy was illuminating inasmuch as each patient in a group of venereophobes could appreciate that his fellows were in fact uninfected and ought to accept reassurance on this point, but each insisted that he himself was the exception, so it did not do much good. In despair and with great reluctance I came eventually to hand my cases one by one over to the electrician, and I was struck (and inwardly dismayed) by the gratifying results. After the first treatment, patients who had been wont to mope about in corners I heard whistling in the corridors and joining in the singing in the ward kitchen. They asked for more of these treatments, feeling that it was doing them good. They did not lose their phobia at once. First all they found themselves forgetting it for hours at a stretch.

They could lose themselves in a movie or at their occupational therapy. The phobia, although still present in the background, had lost its power to hurt so deeply. I never heard a patient claim that he was cured completely. He would say, 'I think I shall get over it in time now.' These patients did not know that they were being subjected to convulsions. They had had 'pentothal' sessions previously and were allowed to believe that the electric current produced a similar 'sleep treatment'. It may sound profoundly silly, but I could only account for the curative effect of ECT in these cases somewhat on these lines.

Here are these chaps whose super ego (part of which I am told dwells in the unconscious) cannot forgive them for their lapses from virtue. They feel they deserve syphilis and they insist on having their deserts. They insist on punishment. ECT supplies that alternative punishment which gives their unconscious just the kick in the pants that it is seeking. This curious hypothesis gained colour from the fact that patients who actually do get infected rarely develop venereophobia, which they could show by refusing to believe themselves cured when smeared, WRs etc., were eventually pronounced negative. Granted that some of the obsessional potential venereophobe type occasionally do get infected, one might assume that these lucky ones accept VD as their punishment, treatment as penance, and the final negative tests as absolution. (I say 'lucky ones,' because I know no condition of suffering so dire or so 24 hours a day as that of venereophobia.)

I do not see (*pace* Dr Winnicott) why ECT should be equated with death any more than sleep or narcosis should be. I feel that it is equated with punishment, and I shouldn't be a bit surprised if many of the more disagreeable but successful orthodox surgical procedures owe their success in part to a similar somato-psychic exchange—I am, etc.,

Mundesley Norfolk.

GEORGE DAY

SIR,—I would like to endorse most heartily Dr D W Winnicott's article (May 17, p 688). I was one of the first to use the ECT treatment in Eire outside of the mental hospitals, early in 1943, and could have added considerably to my income as a psychotherapist thereby had I not quickly realized that its use was merely another attempt to short-cut cure and did nothing to solve the patient's real problems. I was later required to use ECT in a mental hospital for a year, and I became fully convinced that any change which resulted was psychological, and frequently only temporary, and tended to obscure the real issue of the causes of the patient's disappointment and despair. I clearly recall two so-called menopausal depressives who were elevated to apparent normality, and who quietly committed suicide within a year.

I came to regard the ECT switch as a whip in the hands of the operator which could be of value when the patient had intellectually come to a knowledge of his or her problems but was very fearful of taking the necessary steps to solve them. A whip, however, is not a scientific instrument. Need one add more?

Pari passu, Dr J Dunne, the medical superintendent of the Grangegorman Mental Hospital, Dublin, informed me in 1944 that their statistics showed that the relapse rate after insulin treatment for schizophrenia was greater than among those left to recover spontaneously. Grangegorman Hospital had the staff to continue treatment all through the war, so that their statistics were to some point.

ECT and insulin treatment appear to be first cousins, if not full relations—I am, etc.,

Stockton-on-Tees

L F DONNAN

SIR—In his paper on the physical therapy of mental disorder (May 17 p 688) Dr D W Winnicott says "No one has the slightest idea how it works." I can't help wondering whether this is because, expecting complexity, the explanation is actually so simple that it has been disregarded. I believe the prototype of the therapy can be seen in the customary and familiar treatment of a minor hysterical disturbance by a severe sharp admonition. Sometimes slapping the face is recommended or even a douche of cold water. The important thing is to shock the patient by the unsympathetic treatment received from the external world. Clearly such simple measures would not

suffice for the graver psychoneuroses or depressions. I think the principle is the same, but it has to be properly checked up. A pail of water can't be emptied on an unhappy head by appointment. But it is different with ECT. Little is done to mitigate the patient's apprehensions. It may be better to augment them. In any event the convulsion is unpleasant enough—truly an unsympathetic external world. The contributory help of the "suggestive" value of electrical treatment or insulin or whatever it may be should not be underestimated. Ultimately one has to depend on the body's spontaneous power to restore itself. Nothing can be put in by ECT or psychotherapy that was not there before. It is useless to treat a mental defective by these methods.

The value of physical treatment to set working innate powers may be seen in the successful manipulation of an inert flaccid, white, and asphyxiated newborn baby. Nobody who has seen such a one quickly change into a pink bundle of loveliness will ever forget the transformation. But nothing has been done except to stimulate the infant to work as it was meant to, and this is generally as far as interference should go. So with convulsion treatment, the best it can do is to push the patient on to the right road without doing any harm. The psychoanalyst can do no more. He often won't do as much.

The search for first causes is vain. It has not prevented the use of the sulphonamides or penicillin, although their mode of action is not clear. If the physical therapy of mental disorder, shorn of such horrible excrescences as leucotomy, can help it should not be discouraged. Even it might be worth while to extend it to the treatment of the amorphous miscellany of chronic diseases. It might take the place of the various kinds of "shock treatment"—TAB, intramuscular injections of milk, malaria, and the rest—the idea being to jerk the natural powers of restoration into activity where the changes are not irreversible, and it is surprising how often they are not—I am, etc.,

London SW1

E GALLOP

SIR—Empiricism is like a red rag to a scientific bull according to Dr D W Winnicott whose paper, "Physical Therapy of Mental Disorder" (May 17, p 688), will undoubtedly stimulate considerable discussion. It is clear that Dr Winnicott is opposed to empirical treatment, yet he admits that "scientists regard empiricism as a stimulus to research" and that "convulsive therapy attracts to mental hospitals people with first rate qualifications." He stresses that "the doctor is expected to represent science or objectivity," but the title of his original talk was "Some Reasons for a Personal Prejudice against the so-called Physical Therapies of Mental Disorder." How can he reconcile his medical responsibility to be *objective* with his avowed personal prejudice? He suggests that his approach to the problem of physical therapy may be unscientific, but condones his attitude "as a suitable one in the case of such unscientific methods of treating the disordered mind." Surely he does not expect to convince anyone by being unscientific about the unscientific.

If we were condemned to *understand* before we *acted* our instinctive responses would find no expression and many of us would thereby fail to survive until such time as we had managed to acquire experience and psychological insight. May we not justifiably equate empirical therapy with our instincts, which we subsequently endeavour to harmonize with our environment? Stability, maturity, and understanding do normally accrue. Science was evolved from the study of items and phenomena and our knowledge has been derived as much from the observation of the extant as from the development of an idea or the investigation of a theory. Empiricism has its place in modern therapeutics. Those who decry it for such few measures as can be reconciled with absolute scientific criteria are confining themselves in a therapeutic wilderness and failing in their duty to suffering humanity.

For many years the treatment of mental disorders consisted of confinement in an institution, physical restraint and forcible feeding when necessary, and the exhibition of crude sedatives. The therapeutic approach of alienists was just as negativistic as were the clinical signs of some of their patients. Small wonder that quasi-physical measures of an empirical nature were enthusiastically adopted by the successors of that unhappy and frustrated generation. Nevertheless, over optimism and

precipitate recourse to therapy which is not understood must be guarded against and the older orthodox methods must not be discarded too readily because it is easier 'to press a button'. Let empiricism proceed along scientific lines and let us avoid its becoming the whipping boy of those colleagues whose unconscious guilt (over therapeutic impotence) determines a sanctimonious resistance to therapeutic innovation—I am, etc.,

London W 1

ELLIS STUNGO

SIR—The restatement on a systematic basis of arguments which have led Dr D W Winnicott (May 17 p 688) to become a fervent opponent to physical therapy in mental disorder deserves a thorough consideration on its merits. Physical therapy in mental disorder is deprecated and stigmatized as being 'unscientific' and encouraging the belief in 'magic'.

It is doubtful whether some of the summary statements advanced by Dr Winnicott on this subject will come to hold a place of distinction in the realm of science. "Mental disorder is a disorder of emotional development." Does Dr Winnicott exclude from mental disorder degenerative processes (arteriosclerotic and senile) or toxic-infectious psychoses (such as puerperal, choreic, and others) or the post-encephalic personality changes? "False theories are built around the assumption that the mechanism by which change is brought about is a physical one." Dr Winnicott's view seems to be firmly encapsulated in a closed system of mental causality which does not allow for interaction with physico-chemical agencies and ignores the dynamics of psychosomatic unity. None of the great psychological theoreticians who have laid the foundations of mental science (Kraepelin, Janet, Bleuler, Freud) would ever have adhered to such a dogmatic view. Changes brought about in the brain by electrical shocks cannot be fundamentally different from changes produced by chemical agents like alcohol, insulin, benzedrine, etc. Dr Winnicott might as well extend his wrath to include also narco-analysis, which proved so helpful in restoring the psychiatric casualties of the battlefield much quicker than any psychoanalyst could have undertaken. If links are missing in the hypothetical structure underlying physical treatment in mental disorder, it does not mean that such a hypothetical structure must be dropped as valueless. Hypothesis and scientific exploration are necessary correlates.

Not less detrimental than ill-considered summary statements is the monopolizing tendency shown in Dr Winnicott's identification of "scientific psychology" with psycho-analysis to the exclusion of any other approach. In order to proceed scientifically attempts would have to be made at a confrontation of sufficient numbers of cases which have failed on ECT and have responded to psycho-analysis with those in which the result was reversed accompanied by a thorough investigation of all factors involved (not excluding psychological 'epiphenomena' connected with 'submission' to shock treatment). It will be one of the tasks of the regional centres of psychiatric research, to the establishment of which we are looking forward and the existence of which is indeed a desideratum of a high order, to arrange comprehensive and statistically significant investigations into the relative merits of various forms of psychiatric treatment.

While Dr Winnicott points out the fearful reactions of patients to ECT he forgets to mention that the revelations of psycho-analysis in the form of Oedipus castration, anal and similar complexes are not always highly enjoyable. In speaking of leucotomy as a "quack cure" (only recently recommended—in cautious terms—by the Board of Control) he does not shy at a slur on a great number of contemporaries. If personal testimony is of any value I can assure Dr Winnicott that in giving ECT and advocating leucotomy in carefully selected cases I have never felt that I have allowed myself to deviate one inch from the principles of scientific psychology nor from a humanistic approach to the roots of human existence.

There is, however, one good point in Dr Winnicott's Cassandra call. The fact that the more or less formidable armamentarium of modern psychiatry might be placed into the hands of young doctors soon after qualification who lacking a basic psychological education, might use the new methods in a too mechanical way, thereby assuming decisions over the fates of sometimes "very valuable" people calls for a constant and ever increasing vigilance in matters of psychiatric education. Dr Winnicott deploras a tendency "away" from scientific

psychology, but, alas, there has not been a sufficient tendency yet, among the rank and file of psychiatrists to move 'towards' a scientific psychology. Psychiatry, now feeling rich and powerful by constantly widening its boundaries will in the end have to give a proper place again to its present Cinderella, psychopathology, which is the theoretical and experimental exploration of the fundamental dynamics of mental processes in states varying from the normal. Only on the basis of such a no-dogmatic foundation of psychiatry shall we arrive at, and finally, present a balanced view of practical methods and their results—I am, etc.,

STEPHEN KRAUSS

Tuberculosis and Diabetes Mellitus

SIR—I read with interest and agreement the article by Drs W R Gauld and A Lyall on "Tuberculosis as a Complication of Diabetes Mellitus" (May 17, p 677) and was sorry to find in it no mention of what, in England at any rate, constitutes one of our greatest problems in the treatment of diabetes with tuberculosis. In most sanatoria there is a lamentable absence of provisions for the proper management of diabetes, both in respect of trained staff and dietetic and laboratory facilities. As a result the advantages of good treatment of the tuberculosis are more than outweighed by the disadvantages of poor control of the diabetes. Experience has taught me that it is often better to keep the patient at home under the care of the tuberculosis officer and a good diabetic clinic than to send him or her to a sanatorium where the all-important control of the diabetes is likely to be forgotten, ignored or, more often just not understood.

The solution of this problem lies in the establishment in each region of at least one sanatorium in which there should be all the necessary facilities for the maintenance of good diabetic control and to which all tuberculous diabetics in the region could be referred for treatment—I am, etc.,

De Morgan's Spots

SIR,—May I congratulate Capt A R Murison, Lieut J W Sutherland and Flying Officer A M Williamson with regard to their article (May 10, p 634) on Campbell De Morgan's spots, which, so far as I am aware, is the only critical analysis yet published dealing with their relationship to cancer. The dearth of literature on the subject is curious considering that they are often remarked upon, and there is unfortunately an abundance of material available for examination. Your contributors may be interested to read an account of De Morgan's spots or 'plaques de Morgan' by Dr A T Brand, of Driffield published in the *British Medical Journal* in 1902.¹ Brand strongly supported their connexion with malignant disease and called them "canceroderms", his views, however, are unsupported by any statistical evidence.

It might be thought that there would at least be no difference of opinion about their histology, but Sir John Bland Sutton, discussing the structure of De Morgan's spots, said "They are patches of pigment not naevi." With this in mind I once excised and examined a number of the spots but could find no trace of pigment. Their structure is that of a capillary haemangioma—I am, etc.,

Pemphigus Vulgaris

SIR—I have under my care a very severe case of pemphigus vulgaris. In a recent article in the *Archives of Dermatology* successful results are reported after transfusion with blood from persons who have recovered from the disease. Though it is not proved that the success was due to specific properties of these sera, I feel it imperative to try the method, if it can possibly be achieved in view of the extremely grave prognosis. If, therefore, any doctors know of the whereabouts of any patients that have recovered from true pemphigus vulgaris, I

Vitamin Therapy - its uses and limitations

SEBORRHOEIC DERMATITIS

especially when occurring in the region of the naso-labial folds and when associated with cracking of the lips and conjunctivitis, may be an indication of mild riboflavinosis, not uncommon in this country at the present time when foods containing good supplies of riboflavin are in short supply.

The vitamin is available in tablet form. Since however these deficiency signs frequently accompany indications of other B-complex deficiencies, it may better be given with other factors in a combined preparation.

BEFORTISS B-complex capsules

Each capsule contains

nutritional routine for motherhood

For practical reasons it is rarely possible for the diet of the pregnant or nursing woman to provide adequate amounts of all the nutritional factors she requires. Three factors especially needed—iron, calcium and vitamin D—are very commonly deficient in her food.

Calceferum Tablets have the specific purpose of preventing a significant lack of iron, calcium and vitamin D at the time of increased need.

Four Calceferum Tablets supply 25 mg of ferrous iron, 0.5 gram of calcium and 2,000 I.U. of vitamin D. This daily dosage is a routine easily adopted by every pregnant and lactating woman.

Calceferum Tablets are reasonable in price and being chocolate coated are pleasant to take.

The Control of Bacterial Infection with

'SULPHAMEZATHINE'

'Sulphamezathine', officially known as Sulphadimethylpyrimidine B.P.C., is a dimethyl derivative of sulphadiazine and, like the parent substance, has a wide range of antibacterial activity. In addition it possesses a number of relative advantages which are of great clinical importance.

Noteworthy features of the administration of 'Sulphamezathine' are the almost complete absence of toxic after-effects and the rare occurrence of renal complications. The drug is rapidly absorbed and relatively slowly excreted, so that adequate blood levels are readily achieved and easily maintained by comparatively small doses.

In pneumonia, meningitis, haemolytic streptococcal infections and *Bact. coli* infections of the urinary tract treatment with 'Sulphamezathine' has proved particularly effective.

Powder Bottles of 25 grammes, 100 grammes and 500 grammes

Tablets 0.5 gramme Bottles of 25, 100 and 500.

Ampoules (Sodium Salt in Solution)

Water and Salt Depletion

SIR—There are some reactions affecting the distribution of salt which seem to need further study. After the masterly presentation of the role of salt in the body by Dr. H L Marriott (Feb 15, March 8 and 15) one hesitates to intervene and can only plead interest as an apology. The reactions in question involve the little-explored field of the absorption thresholds of colloids for different concentrations of electrolytes. To illustrate Gelatin placed in cold water swells. If salt be added gradually the gelatin continues to swell until a critical point is reached, then if more salt be added it will abstract water from the gelatin. Finally the salters' process is reached, used for centuries to cure skins. The significant points are that for each concentration of the electrolyte there is a different degree of absorption, and when this is active the force developed against resistance is very great. This pressure is masked in the body by elasticity in the tissues. In an organ with a capsule, like the kidney, it is greater, the rock is split. Evidently the force of colloidal absorption cannot be ignored.

Its action in the body is shown when oxyhaemoglobin is converted into the carboxy form. This causes the venous blood to absorb from 5 to 10% of its bulk of water, aiding the venous circulation and that of the tissue fluid. The water is released in the lung and excreted mainly by the kidney. That the absorptive capacity of the colloid is not exhausted is shown by the fact that in cases of suffocation the bulk of the venous blood is increased by 30%.

The typical cell is stated to retain potassium and phosphorus, but contains little salt although bathed constantly by a solution of it. The differences in the other types of cell must be due to some extent to the colloids they contain. The admission cells of the kidney pass most electrolytes in solution but refuse feebly-ionizable proteins and neutral glucose. The conservation cells of the organ absorb water and salt, which they return to the blood freely, but refuse all other constituents of primary urine. Why does the colloid of one cell combine with potassium which another refuses? Why does the earth retain potassium while salt is washed into the sea? Apparent suspension of the laws of osmosis is evident in different reactions. During life the cell excretes actively but when dead ceases to do so but absorbs avidly. Why is osmosis active in dead cells but not in the living? Why does the cancer cell absorb so rapidly as to cause pressure which favours cell division?

If a red blood cell be filled with molecules the extent of its internal surface can be expressed in square metres. As electronic change is interatomic rather than between molecules, the area at which surface interchange, the base of chemical action, can take place is very great. Considering the diversity of action in the cell, which is so small that we know but little about it, it must be the seat of intense activity, much of which must be maintained by colloidal surface. The little explored field of colloid absorption does seem to need investigation—I am, etc

Montreal

RICHARD KERRY

Prognosis in Acute Nephritis

SIR—Several statements are made in the interesting survey (April 5 p 457) of Rudebeck's important paper on the prognosis in acute nephritis that seem to me to require qualification and upon which I would venture to comment.

After remarking that the prognosis must be guarded if residual symptoms are present on discharge from hospital (with which I agree) it is stated that if they (i.e., residual symptoms) persist for more than one year or are severe, chronic nephritis may confidently be awaited. With this I cannot agree. In the paper by me cited in the annotation and by Rudebeck I referred to 586 patients with war nephritis in whom residual symptoms persisted for from one to ten years after the onset, all of whom eventually recovered completely. While the majority cleared up spontaneously in the earlier part of this

period, in 14 patients residual signs finally disappeared only in the ninth and tenth years after the onset.

It is, I believe, generally agreed that the prognosis in war nephritis differed little if at all from that in glomerulo nephritis in civilians of comparable ages. In the past twenty-five years I have certainly seen quite a number of civilian patients of all ages in whom residual signs persisted for years who eventually recovered completely as judged by standards not less rigorous than those used by Rudebeck. On the other hand the proportion of patients suffering from latent or, as I prefer to call it "unresolved" nephritis that ultimately recover is undoubtedly small. Those who do recover are fortunate exceptions. Nor in my experience is it correct to assert or to imply that chronic nephritis inevitably ensues when residual symptoms are severe for I have often seen patients recover completely with appropriate treatment who were suffering from massive albuminuria with anasarca and ascites that had persisted for more than a year after the onset of the disease and before treatment was instituted.

It is not necessarily, in my view, the severity of the residual symptoms that determines the issue, but their nature. When they include hypertension or diminished renal function, however slight, and these persist for a year, and often for less than a year it is a very different story. It is doubtful if complete recovery ever then occurs. I believe that hope of eventual complete recovery should never be abandoned however long residual signs persist, provided these do not include hypertension or diminished renal function especially the former. The continuance for more than three or four months after the onset of considerable and undiminishing numbers of red blood cells in the urine is also in my experience a sign of grave import.

The second point to which I would refer concerns the effects of prolonged bed rest on the ultimate prognosis in this disease. In referring to Rudebeck's conclusions it is stated in the annotation that "it could not be proved that the prognosis was any better if the patient was kept at rest (i.e., in bed) for long periods. On consulting the original paper, however, I find that only 50 of the patients in Rudebeck's series were confined to bed for more than ninety days and only 7 for between six and nine months. Seven patients in the series were regarded as cured on discharge (not those who were confined to bed for the longest periods), and 43 were classified as not completely recovered. Concerning the latter Rudebeck remarks "among the non recovered cases we also meet with many in which bed rest may be designated as insufficient." I entirely agree.

Observations extending over many years, but particularly during the past five years in the Renal Unit at Pembury where it is possible to keep patients in bed as long as is considered necessary, indicate that complete recovery from unresolved nephritis results more often than is commonly supposed from treatment in which prolonged confinement to bed is probably the most important factor. In many patients six to nine months' carefully regulated bed rest is not the maximum but the minimum period required to achieve success. So far as I am aware the potentialities of prolonged and accurately controlled bed rest in renal diseases have not previously been systematically exploited on any adequate scale. The effects are of course quite different from those seen in patients who languish in bed in their own homes or in hospitals where bed rest is prescribed more or less as a matter of routine. Our experience at Pembury where the objective evaluation of the effects of this measure has been a main line of research for some years indicates that it may well prove to be as important in the treatment of unresolved nephritis and some other forms of renal disease as it is in pulmonary tuberculosis, for example. That prolonged and properly controlled bed rest for from six to fifteen or twenty months is sometimes the only means of procuring complete and lasting recovery in unresolved nephritis I have no doubt though there is little to suggest that this measure will prove successful in more than a small proportion of these cases. In the absence of any speedier or better method of treatment it seems right to urge that patients suffering from unresolved nephritis should be given the chance of permanent recovery, however slender, that adequate bed rest occasionally offers—I am, etc,

Pembury Kent

A A OSMAN

State Medical Service in New Zealand

SIR—Sir Ernest Graham Little (May 3, p. 611) quotes a paragraph from an article by Mr. A. E. Porritt in the *St. Mary's Hospital Gazette* 1947, 53/54 as a warning against any form of national medical service. I have now obtained the last two numbers of this gazette and find that this quotation is a single paragraph taken from one of two long articles describing Mr. Porritt's travels in America and New Zealand. They are obviously written to amuse and instruct his students. I should imagine that the last thing Mr. Porritt expected or desired was that any part would be removed from the obscurity of an almost private publication and publicized as serious political or medical comment.

As one who has spent four months in that delightful and friendly Dominion during the same autumn when Mr. Porritt paid his shorter visit, I understand what was in his mind when he wrote that paragraph and I should be surprised if he did not now regret having expressed himself so tersely that it allows of his being quoted in a sense which I feel sure is not his true appraisement of the medical position in New Zealand.

Let me take Mr. Porritt's criticisms in detail.

(a) 'a slightly improved all round service for the public during business hours. To get a doctor in New Zealand after 6 p.m. and over week-ends is not an enviable task.'

This is really commendation of the service with criticism of the number of doctors who administer it. To a large extent this criticism is true. Now that the doctor's fee, or part of it, is paid by the Government, there has been a great increase in the number of people seeking medical advice and, unfortunately, this Act came into operation while many of the profession were in the Services. The result has been great pressure upon those practitioners still in practice, but this position will rectify itself as the number of these increases.

(b) 'a definite falling off in the standard of medical practice both from ethical and clinical viewpoints. This is the consensus of opinion from all branches of the profession.'

Having so recently visited New Zealand I know what is in Mr. Porritt's mind, though I think he would have expressed it differently if he had intended it to be made more public, as I feel sure that he was regaled with stories of the activities of certain practitioners just as I was. Ethically every country has its black sheep, but I found that these stories told in every centre generally referred to the same small group of practitioners, and finally I came to the conclusion that New Zealand has a smaller percentage of black sheep than we have to endure. Clinically New Zealand practitioners consultant and general, have the same high standards as always, both the clinical and ethical failures referred to the same small group. I only wish ours was as small.

(c) 'a growing and already appreciable dearth of specialists, and this in a country where the proportion of men taking higher degrees was previously exceptionally high.'

Here again I imagine that brevity has failed to express the true state of affairs. In most hospital appointments I think that there are just as many well trained candidates as in the past. It is true that there is a dearth of specialists in certain branches notoriously in my own, but this is due to the ancient method of hospital administration, which fails to create the necessary posts, and this is unrelated to the Social Security Act.

What I think Mr. Porritt has in mind is that there may be a dearth of well trained men in the future, as at the present time newly qualified men are tempted to rush into general practice where they can immediately make what to them is a large private income, rather than devote years to postgraduate training and the obtaining of higher diplomas. This is well recognized by those responsible for medical education in New Zealand and is a cause of anxiety. Apart, however, from any action to be taken by the authorities, this condition will gradually rectify itself as the number of general practitioners increases and patients again have greater freedom in the choice of doctors.

Like all new large schemes social security in New Zealand has much to be commended and probably much to be amended, and it seemed to me that professional anxiety was chiefly as to the form amendments would take. Of one thing I can assure Sir Ernest Graham Little the general practitioner in New Zealand would view with consternation the complete cancel-

lation of the medical part of this Act. It will be understood that any opinion expressed in this letter refers only to New Zealand and its Medical Service—I am, etc.,

Manchester

WM. FLETCHER SHAW

Classification of Tuberculous Patients

SIR—For a long time workers in tuberculosis have been awaiting an authoritative lead from the Ministry of Health in the matter of classification of the disease at the time of diagnosis and also regarding assessment of the results of treatment. Local authorities and others are now informed that the Minister has decided to adopt recommendations made to him by the Joint Tuberculosis Council, which are issued as a substitute to Section I of the Appendix to Memorandum 37/T (revised).*

Cases to be classified 'quiescent' after treatment are described in part, as those 'in which no tubercle bacilli have been found on three consecutive monthly examinations by stained film'. It would be of considerable help to one tuberculosis worker if the Joint Tuberculosis Council or the Ministry of Health would indicate precisely or even vaguely, what they are talking about. Do they refer to sputum examined by any staining method and anybody? Do they accept a specimen of saliva from which pus is absent as suitable material for examination? Do they recognize that pulmonary secretions which are not projected forward beyond the posterior third of the tongue are swallowed? Is it their intention to ignore for the purpose of future classification the fact that more precise methods of search for tubercle bacilli exist and are in everyday use? If so, the inference seems plain enough—that it is not possible in their view, to eliminate all tubercle bacilli from secretions, and we are to rely for prognosis on a crude and discredited investigation—I am, etc.,

Day Nurseries

SIR,—Those members of the profession who are interested in the practical, as distinct from the theoretical, aspects of the care of children in nurseries seem to be doomed to recurrent disappointment in our hopes for really useful and dispassionate information. Dr. McLaughlin's paper (May 3 and 10, pp. 591, 631) began well and promised just the kind of information which is needed, but it declined in its later stages into a mere restatement of the obvious without any attempt to evaluate the findings which were stated.

Dr. McLaughlin certainly deserves congratulation on one point, she has tried better than her predecessors to obtain figures which are statistically valid. Even so, allowance ought to be made for two factors which will bring about a certain amount of selection in the 'Nursery' and 'Home' groups. A considerable proportion of nursery children come from homes in which there exists economic necessity for the mother to work. It is not improbable that those children have had a less satisfactory start in life than the 'Home' group. Further, it would appear that something like 10% or 15% of the 'Home' children failed to attend for examination, it is not unreasonable to assume that the absentees were largely the children of the more careless parents and that a group of children who might have pulled down the 'Home' averages was missing.

This investigation, like those which have preceded it, pays attention to nasopharyngeal infections and the incidence of tonsillar enlargement. Surely it is time that we learned to be realistic in considering these two conditions. Tonsillar enlargement is becoming generally recognized as of no pathological importance in itself. There is, moreover, every reason to believe that it occurs as a part of the child's normal development of immunity. In more than a dozen years' experience of work with nursery, nursery school, and nursery class children I have found tonsillar enlargement to be a constant phenomenon which appears on a child's first admission to group life, whether this happens at the age of 2 or the age of 5 and which gradually disappears as he becomes habituated to dealing with infections. Almost equally common is a phase of recurrent minor respiratory infections, lasting between six and eighteen months and then disappearing.

So far in fact as respiratory infections are concerned the effect of nursery life is simply to anticipate an inevitable

occurrence of childhood. This may be unimportant or it may not, but it cannot be dismissed as bad without further evidence. What is the later history of the nursery child? Surely we need to know whether there is any evidence of lasting later damage before we attach any importance to the increased incidence of these infections. A similar criticism may be applied to Dr McLaughlin's comments on measles. Obviously the aggregation of children during a measles epidemic will increase infection. But it is futile merely to say, as Dr McLaughlin does, that 'this is particularly important in view of the greater mortality rate of measles in young infants and the greater risk of serious complications.' Did the 111 nursery children with measles show a greater than average rate of mortality and complications? If not, the greater incidence of infection loses its importance.

Every investigation of the health of nursery children so far carried out has been subject to two fallacies. The first is the assumption that a medico social problem can be solved in terms of clinical medicine alone—the fact that the social aspects of nursery life are difficult to evaluate is no reason for ignoring them. The second is the comparison of the nursery child with the child from a normal home—true comparison would lie between the nursery and the home which would house the particular child if the nursery were not there. Perhaps 50% of nursery children would, if the nursery were not available, have to live in home surroundings of a grossly unsatisfactory character. Nurseries are a social remedy for social ills. Presumably what we need to know is whether the remedy is, in fact, worse than the continued toleration of the ills and what more satisfactory remedies can be found. Even such a thorough and workmanlike piece of research as Dr McLaughlin has produced will be comparatively sterile unless its application to these practical problems is pursued—I am, etc.,

Colchester

JOHN D. KERSHAW

SIR—Your leading article of May 10 (p. 644) on day nurseries reflects the attitude of many recently published articles and letters. As the mother of a child who has attended a day nursery, and having worked in one myself, I am hesitant to become an advocate of any system which tends to sever the relationship between mother and child, but it should be borne in mind that a large percentage of mothers taking advantage of available day nurseries are wholly or partly responsible for the financial cost of the child's upbringing. This may arise because (a) the child is illegitimate and the putative father unknown, (b) the father is dead and the mother not in receipt of a pension or the pension afforded to her is inadequate in view of the high cost of living, (c) the father has deserted the mother and falls in arrear with his payments towards their keep. I know of many cases where the endeavour to trace the husband and to seek legal aid for the recovery of arrears or to re-establish the allotment is beyond the capability of the mother. I would add to these those instances where the husband's earnings are inadequate and the mother has real need to supplement his income with her own earnings.

If day nurseries are not available to such mothers the only alternative is to find a foster mother and whereas an intelligent nursery worker can supply the child's needs during the day with affection and sympathy without impairing the child's relationship with its mother a foster-mother often accepts the charge either for financial gain or because she has no children of her own and finds an outlet for her maternal instinct. The former reason and its effect on the stability of the child's environment need no comment. The latter is fraught with difficulties, and in many instances the foster mother receives the child's affection and the mother becomes a tolerated visitor.

Unmarried mothers to day can arrange to have their babies adopted and there are numerous children's homes willing to admit destitute children but the mother who chooses to keep and maintain her child is worthy of consideration. Some nurseries have waiting lists of children for admission, and the mothers suffer very real hardship while unable to work. Is it not possible to give priority to those mothers who have real need to work rather than to those who desire to escape maternal responsibilities for less harrowing work in factories?—I am, etc.,

MARGARET WIGFIELD

The Revolution in Anaesthesia

SIR,—With the letters of Drs Massey Dawkins and H. W. Loftus Dale (May 10, p. 654) it is to be hoped that the trumpet has sounded the retreat from the indiscriminate use of curare by anaesthetists. Common sense and common professional prudence may now return. It has indeed been disconcerting to hear of this highly lethal drug being used, with no other excuse than that it facilitates the passage of endotracheal tubes, for operations requiring little muscular relaxation at all.

Surgical shock has not changed its nature since the administration of curare has become all too common. The degree of shock a patient suffers from a surgical operation depends on many factors, but the chief of these remain (a) the patient, (b) what is done to him, (c) how it is done and by whom. Under the latter head come both surgeon and anaesthetist.

It is common experience to find that of two sailors falling into a dry dock while returning to their ship after dark the drunker (and more relaxed) sustains less shock and fewer fractures. Nevertheless he will die if the fall has been far enough, even if he be both "pentothalized" and "curarized" before taking the plunge. This lamentable truth applies also to the patient's plunge into anaesthesia, that 'little death,' and into surgery, especially the exploratory type of surgery which so often becomes a boisterous rummaging into what was once called the sacred temple of the human spirit. We all know the surgeon whose cry is 'Iron them out,' and we have all at times wondered whether he would really be happier with his head inside or whether he is better playing a querulous tune with the parietal peritoneum as his banjo string.

When a bull is loosed in a china shop it is fortunate if a few of the more valuable pieces have been kept on the high shelves. Only thus can complete wreckage be avoided. The bovine comparison cannot, we must admit, be confined to the surgical fraternity. One correspondent points out that the only case of shock he recalls when using curare was when he inadvertently failed to notice that his soda-lime absorber was not functioning. It is fair comment to remind him that, had he not been using curare as a short-cut solution of his relaxation problem, the fact that he was submitting his patient to auto-intoxication in addition to the exogenous poisons could scarcely have escaped his attention.

Curare is a great help in the special case, but I beg leave to doubt whether surgical and anaesthetic techniques have improved with its indiscriminate use—on the contrary, humans being what we are. This drug is indeed a milestone in anaesthesia, but do not let us allow it to produce irreversible relaxation in too many patients who might well have survived had it remained in the South American blow pipes—I am, etc.,

Derby

ANDREW G. HEGARTY

Spinal Anaesthesia

SIR,—Regarding your interesting comments on this subject in your current issue (May 10, p. 647) may I be permitted to advance a purely personal theory, entirely without laboratory or indeed any kind of scientific support that appears to me to be relevant? It is this. No mention is made regarding the normal procedure, adopted by myself over many years and, I think, the majority of anaesthetists of (alas) the older school, of smacking the skin with a scalpel (after the introduction of the ordinary preliminary local anaesthetic, with or without adrenalin or whatever it may be) before the introduction of the needle. I submit, Sir, that unless this precautionary measure is adequately carried out there is every danger of the needle failing to make an absolutely clean puncture and acting after the manner of a cork borer, carrying into the theca a minute piece of skin, with disastrous results despite the most painstaking routine sterilization.

I write, Sir, purely in the light of long personal experience and in the entire absence of any kind of supporting evidence. But the idea is well worth while bringing forward by the courtesy of your columns especially to-day when most of us are using worn and blunted instruments with badly fitting and bevelled obturators that would appear to invite trouble—I am, etc.,

Worthing, Sussex

O. P. CLARK

Penicillin

SIR—Recently you have made annotations on the dosage of penicillin (April 19, p 536) and the lack of immunization in infections treated early by this drug (May 10, p 648). In both cases, I think there is shown a feeling of disappointment that recurrences sometimes occur and show that infection has not been completely eradicated by large doses of penicillin. This view is due to an unreasonable dependence on drug treatment alone. When the drug is in direct contact with sensitive bacteria it is effective in very small quantities, so that the large amounts injected by Dr D P Whentley (April 19 p 530) for styes, boils etc., are very wasteful although convenient for ambulant patients.

It is likely that some bacteria escape the direct action of the drug in all cases and the risk of these causing lesions later depends on their numbers and the patient's resistance by serum and tissues. The danger is greatest when living organisms are left in unobserved positions and when resistance is low. Increasing dosage is not enough, on the other hand, delaying administration so that the immunity processes may be stimulated is dangerous in serious infections and is uncontrolled and is likely to be ineffective when resistance is poor. Penicillin should be used in solutions or powder locally if important lesions can be reached, and dosage should allow for absorption into the general circulation if necessary (Florey, M E *et al*, *Lancet* 1946, 2, 405). As an alternative, if no local lesion is prominent, or additionally if required, systemic injection of the drug may be needed. It is very important that if lesions recur latent primary sources of infection should be sought actively and drained or surgically removed and that resistance should be increased by vaccines, non specific protein therapy, injections of arsenic or other means. To rely too much on penicillin can bring discredit to the drug and the doctor, but a more careful use of it will reveal the immense problem of people whose susceptibility is very great to small numbers of organisms which reach them from outside or have remained from previous illness—I am, etc.

J M ALSTON

Vaginal Operations

SIR—I would like to point out that Dr J H Hannan in his letter headed "Vaginal Operations" (May 3, p 614) made a statement which is not, I am afraid, in accordance with the facts. He says "carcinoma of the vaginal portion of the cervix only occurs in women who have been pregnant".

Two series of published figures will be enough to prove this point. (1) Fricker R E (*Proc Staff Meetings Mayo Clinic* 1939, 14 705). A series of 108 "stump" carcinomata, 21% of which were in women who had never been pregnant. (2) Hurdon, E (*Cancer of the Uterus* London, 1942). There is a graph on p 3 showing the mortality rate for England and Wales in cases of cancer of the uterus at different age groups, single and married women being graphed separately. (There is a footnote pointing out that about 90% of these are cervical cases.) At nearly every age group the cases in single women are about half the number in married women (rather less in the lower age groups)—I am, etc.

Manchester

T F REDMAN

Cows' Milk and Rheumatism

SIR,—When visiting the north of Scotland lately I met a veterinary surgeon of great acumen and well known for his skill in dealing with diseases of domestic animals, and was surprised to learn from him that cows are liable to acute rheumatic arthritis, with swollen joints, and that they may develop valvular affections of the heart. He added that he prescribed salicylate of soda in spoonful doses thrice daily for the disease.

I saw at once that if this were so we had a rational explanation of the disease in human beings, as cows' milk would readily convey the infection. I am not aware that this conception of the origin and spread of rheumatic fever is mentioned in any of the textbooks on medicine. Should my friend's observations and experience of acute rheumatism in cows be confirmed, we have here an important contribution to practical medicine, and the obvious conclusion is that every cow considered to be

suffering from acute rheumatic arthritis should be reported to the medical officer of health so that measures should be taken to abolish the infection. I have pleasure in stating that the name of my accomplished friend is Mr Duncan Campbell, Veterinary Surgeon, Thurso NB—I am, etc.

Glasgow

JOHN T MACLACHLAN

Acid Drinks and Sulphonamide Therapy

SIR—Dr Petronella Potter in her letter (May 10, p 654) recommends the prohibition of acid fruit drinks for patients on sulphonamide treatment to avoid renal complications. May I point out that her recommendation is based on the entirely erroneous conclusion that acidity of fruit juices leads to an increase of acidity in the urine? Rather, the opposite is the case. The acidity of fruit juices is due to weak organic acids which in the urine at the end of a metabolic process are excreted as alkaline carbonates and so increase the alkalinity of the urine. There is, therefore, no reason for depriving patients on sulphonamide treatment of these refreshing drinks—I am, etc.

Warwick

A HOLZEL

Handling of Food

SIR—A question has been puzzling me for some time now, and recent events locally have brought it to my mind. It is this: How is it that the authorities local and central, permit our food, particularly meat to be handled as it is to day?

I have always understood that the English public health laws have been among the finest, if not the finest, in the world, and that these laws lay down that meat must be delivered to the retailer in clean vehicles by men wearing clean washable caps, overalls and aprons and that the meat must be hung a certain minimum height from the floor in such a position that customers and passers by do not come into contact with it. How is it then that one sees meat being delivered in vans that certainly do not look clean, by men wearing old serge uniforms and no aprons or overalls, and that it is dumped down in the corner of the shop on the floor?—I am, etc.

Coventry

JOHN HALE POWER

Another Name

SIR,—During this war in my experience in the Far East many "new" psychiatric conditions have been described, or perhaps these conditions were seen earlier than hitherto. The most dramatic of these is the "wartime schizophrenia"—an atypical and usually acute schizophrenia or schizoid episode which has a sudden onset and usually a happy ending brought on by ECT or insulin therapy or the two combined. As part of this syndrome there is often a distressing awareness of mental illness. This awareness does not amount to psychological insight, which is defined by Arthur P Noyes in his *Modern Clinical Psychiatry* Philadelphia, 1939 as "an appreciation of the presumed motives and genesis of their [mental] symptoms" self-judgment and the degree to which his [patient's] experience is understandable to him, the manner and extent to which it is interfering with his social adjustment and the successful performance of his usual duties.

Though I am conscious of an already cumbersome psychiatric terminology I feel that adding one further term covering awareness of mental illness "as distinct from insight will be justified if it draws attention to the symptom and leads to adequate study. This awareness of mental illness is distressingly painful to the psychotic, and the mental pain is usually relieved by "shock" therapy, but the awareness persists or, if not present before it appears in retrospect and may lead to full psychological insight.

On a parallel with anosognosia—i.e., unawareness of physical disability—I think the term "abmenognosia" or, in short, "abmenosia," may be adopted. It is perhaps rather a clumsy tongue-twisting word and a little irregular in its Latin, but until another is forthcoming it may serve its purpose.

I should be interested to hear what comments there are or this suggestion and whether it will be acceptable to medical nosology?—I am, etc.

D CAPPON

Silence on the Act

SIR—Yesterday I examined yet another week's *BMJ* without light or leading for ordinary members in the obscurity of their position. And to day an instalment of regulations under the impending Health Act, No. 899, has come into my hands. They have, of course, the force of an Act of Parliament, though all that Parliament has likely seen of them is the printed cover as they 'lay on the table'. Thus the Ministry marches while the B.M.A. stays licking its wounds.

Will the B.M.A. please tell us at least something? Has all thought of a stand gone by the board? The panel system was the last relic of our freedom. Is the B.M.A. going to make a stand for it? The silence of the *Journal* is ominous. So are regulations 899, already "in force". They deal with two oddly assorted matters. They (1) invite a Local Medical Committee, among other bodies, to appoint an original member of the Executive Council of an Area and lay down the procedure of such Councils, and (2) deal with supplementary ophthalmic services.

The eight regulations under the second head perpetuate recognition of the old imperfect sight testing arrangements and do nothing to advance those improvements in them which Bishop Harman with devoted labour, introduced. The sixteen regulations under the first head, recognizing as they do that the Act is in being, invite us to take some immediate part in working it. Have we again deferred our decision to the eleventh hour?—I am, etc.

Holmes Chapel, Cheshire

LIONEL JAS. PICTON

Guidance in Certification

SIR—The profession had some reason for believing that the principal motive of the Health Service measures contemplated in the Beveridge Report was the desire to control medical certificates in the interest of solvency of the National Insurance Act which was the main objective of the Beveridge Report. Your editorial comments on the increased demand by every Government Department for medical certificates illustrated by some of the trivial examples you quote, have rightly drawn attention to the burden this places upon the profession. But a still more serious development is foreshadowed by a question which appears in *Hansard* (May 15 1947 column 174). A Labour back-bencher asks the Minister of Fuel and Power "what guidance and instructions [the italics are mine] he proposes to issue to the medical profession in connexion with the granting of medical certificates allowing the use of gas and electricity for space heating purposes in residential premises". The Under Secretary was good enough in his answer to say that "he had no reason to suppose that the medical profession do not honourably carry out the heavy burdens which I am afraid we are obliged to impose upon them". But this answer did not satisfy the questioner, who, I fear, would be supported in these suspicions by a large section of the Labour Party.

The greatly increased powers conferred upon the Minister by the new Act would obviously intensify the danger to the profession that certification will in fact be directed and controlled from Whitehall as exemplified by the remarkable admissions made by the Minister of Food with regard to the censorship by lay persons of medical certificates in the allocation of invalid diets—I am, etc.,

House of Commons

E. GRAHAM-LITTLE

No Divorce for Neurosis

SIR—In the case reported under the heading "No Divorce for Neurosis" (April 12 p. 512) the legal argument is interesting. From a layman's viewpoint however, if the wife applied for the separation order, and refused to return to her husband despite his letter and visits, surely she is the deserter and only he would be able later to sue for a divorce.

Neurosis can make normal cohabitation impossible. In insanity the law does not compel the partners to live together. Visits and an affectionate and repentant letter "do not alter the experience nor the fear of days and nights of unreasonable behaviour to which there is no witness"—I am, etc.,

Newell, 100, 101, 102, 103, 104, 105, 106, 107, 108, 109, 110, 111, 112, 113, 114, 115, 116, 117, 118, 119, 120, 121, 122, 123, 124, 125, 126, 127, 128, 129, 130, 131, 132, 133, 134, 135, 136, 137, 138, 139, 140, 141, 142, 143, 144, 145, 146, 147, 148, 149, 150, 151, 152, 153, 154, 155, 156, 157, 158, 159, 160, 161, 162, 163, 164, 165, 166, 167, 168, 169, 170, 171, 172, 173, 174, 175, 176, 177, 178, 179, 180, 181, 182, 183, 184, 185, 186, 187, 188, 189, 190, 191, 192, 193, 194, 195, 196, 197, 198, 199, 200, 201, 202, 203, 204, 205, 206, 207, 208, 209, 210, 211, 212, 213, 214, 215, 216, 217, 218, 219, 220, 221, 222, 223, 224, 225, 226, 227, 228, 229, 230, 231, 232, 233, 234, 235, 236, 237, 238, 239, 240, 241, 242, 243, 244, 245, 246, 247, 248, 249, 250, 251, 252, 253, 254, 255, 256, 257, 258, 259, 260, 261, 262, 263, 264, 265, 266, 267, 268, 269, 270, 271, 272, 273, 274, 275, 276, 277, 278, 279, 280, 281, 282, 283, 284, 285, 286, 287, 288, 289, 290, 291, 292, 293, 294, 295, 296, 297, 298, 299, 300, 301, 302, 303, 304, 305, 306, 307, 308, 309, 310, 311, 312, 313, 314, 315, 316, 317, 318, 319, 320, 321, 322, 323, 324, 325, 326, 327, 328, 329, 330, 331, 332, 333, 334, 335, 336, 337, 338, 339, 340, 341, 342, 343, 344, 345, 346, 347, 348, 349, 350, 351, 352, 353, 354, 355, 356, 357, 358, 359, 360, 361, 362, 363, 364, 365, 366, 367, 368, 369, 370, 371, 372, 373, 374, 375, 376, 377, 378, 379, 380, 381, 382, 383, 384, 385, 386, 387, 388, 389, 390, 391, 392, 393, 394, 395, 396, 397, 398, 399, 400, 401, 402, 403, 404, 405, 406, 407, 408, 409, 410, 411, 412, 413, 414, 415, 416, 417, 418, 419, 420, 421, 422, 423, 424, 425, 426, 427, 428, 429, 430, 431, 432, 433, 434, 435, 436, 437, 438, 439, 440, 441, 442, 443, 444, 445, 446, 447, 448, 449, 450, 451, 452, 453, 454, 455, 456, 457, 458, 459, 460, 461, 462, 463, 464, 465, 466, 467, 468, 469, 470, 471, 472, 473, 474, 475, 476, 477, 478, 479, 480, 481, 482, 483, 484, 485, 486, 487, 488, 489, 490, 491, 492, 493, 494, 495, 496, 497, 498, 499, 500, 501, 502, 503, 504, 505, 506, 507, 508, 509, 510, 511, 512, 513, 514, 515, 516, 517, 518, 519, 520, 521, 522, 523, 524, 525, 526, 527, 528, 529, 530, 531, 532, 533, 534, 535, 536, 537, 538, 539, 540, 541, 542, 543, 544, 545, 546, 547, 548, 549, 550, 551, 552, 553, 554, 555, 556, 557, 558, 559, 560, 561, 562, 563, 564, 565, 566, 567, 568, 569, 570, 571, 572, 573, 574, 575, 576, 577, 578, 579, 580, 581, 582, 583, 584, 585, 586, 587, 588, 589, 590, 591, 592, 593, 594, 595, 596, 597, 598, 599, 600, 601, 602, 603, 604, 605, 606, 607, 608, 609, 610, 611, 612, 613, 614, 615, 616, 617, 618, 619, 620, 621, 622, 623, 624, 625, 626, 627, 628, 629, 630, 631, 632, 633, 634, 635, 636, 637, 638, 639, 640, 641, 642, 643, 644, 645, 646, 647, 648, 649, 650, 651, 652, 653, 654, 655, 656, 657, 658, 659, 660, 661, 662, 663, 664, 665, 666, 667, 668, 669, 670, 671, 672, 673, 674, 675, 676, 677, 678, 679, 680, 681, 682, 683, 684, 685, 686, 687, 688, 689, 690, 691, 692, 693, 694, 695, 696, 697, 698, 699, 700, 701, 702, 703, 704, 705, 706, 707, 708, 709, 710, 711, 712, 713, 714, 715, 716, 717, 718, 719, 720, 721, 722, 723, 724, 725, 726, 727, 728, 729, 730, 731, 732, 733, 734, 735, 736, 737, 738, 739, 740, 741, 742, 743, 744, 745, 746, 747, 748, 749, 750, 751, 752, 753, 754, 755, 756, 757, 758, 759, 760, 761, 762, 763, 764, 765, 766, 767, 768, 769, 770, 771, 772, 773, 774, 775, 776, 777, 778, 779, 780, 781, 782, 783, 784, 785, 786, 787, 788, 789, 790, 791, 792, 793, 794, 795, 796, 797, 798, 799, 800, 801, 802, 803, 804, 805, 806, 807, 808, 809, 810, 811, 812, 813, 814, 815, 816, 817, 818, 819, 820, 821, 822, 823, 824, 825, 826, 827, 828, 829, 830, 831, 832, 833, 834, 835, 836, 837, 838, 839, 840, 841, 842, 843, 844, 845, 846, 847, 848, 849, 850, 851, 852, 853, 854, 855, 856, 857, 858, 859, 860, 861, 862, 863, 864, 865, 866, 867, 868, 869, 870, 871, 872, 873, 874, 875, 876, 877, 878, 879, 880, 881, 882, 883, 884, 885, 886, 887, 888, 889, 890, 891, 892, 893, 894, 895, 896, 897, 898, 899, 900, 901, 902, 903, 904, 905, 906, 907, 908, 909, 910, 911, 912, 913, 914, 915, 916, 917, 918, 919, 920, 921, 922, 923, 924, 925, 926, 927, 928, 929, 930, 931, 932, 933, 934, 935, 936, 937, 938, 939, 940, 941, 942, 943, 944, 945, 946, 947, 948, 949, 950, 951, 952, 953, 954, 955, 956, 957, 958, 959, 960, 961, 962, 963, 964, 965, 966, 967, 968, 969, 970, 971, 972, 973, 974, 975, 976, 977, 978, 979, 980, 981, 982, 983, 984, 985, 986, 987, 988, 989, 990, 991, 992, 993, 994, 995, 996, 997, 998, 999, 1000

G. M. LANGHAM-HOBART

POINTS FROM LETTERS

Toxicity of Iron Compounds

Dr T. PIRES (Weston super-Mare) writes. In reference to Dr Violet Russell's communication (April 5, p. 465) if "massive doses of iron salts are not indicated there is no reason to withhold judicious use of same. The treating of microcytic anaemia with iron is a useful therapeutic measure, whose benefit it may easily be harmful to withhold from patients by a general measure. The precaution to take in prescribing iron is to ensure that there is no constipation and that taking iron does not cause diarrhoea. In other cases there is real benefit from such treatment, especially in times when sulphonamide therapy is so universal a practice. I should like to know whether sodium sulphate (as stated by Mr G. F. Somers in the same issue) is contained in Blaud's pill rather than sodium bicarbonate. As to vitamin concentrates, my finding is that the natural sources are more effective by oral therapy except in the case of vitamin A, perhaps on account of the deficiency of the latter in present-day diets.

Star-gazing

Dr R. CHRISTOPHER HOWARD (London, W.1) writes. Among the minor improvements which might be made by a planned State would be the suppression of the widely disseminated nonsense misnamed astrology. If we are the keepers of the public health, should we not as a profession protest against the publication of misleading balderdash, abjure the heresy that the fault lies not in ourselves but in our stars, and take a firm stand against suggestions that reward is not the result of endeavour? We may humbly and gladly admit the powerful reality of forces whose comprehension lies beyond our fallible power of reasoning, but all these can be integrated for good if, using the beautiful words of Cranmer, we pray that we may be granted those things which for our ignorance we cannot and for our unworthiness we dare not ask.

A "Medical Certificate"

Dr E. ROLAND WILLIAMS (Clynderwen, Pem.) writes. I have before me a particularly objectionable example of the kind of form still used by some insurance companies when a patient submits a claim under a "sickness and accident" policy. The form is of the type which extracts from the practitioner, under the title of a "medical certificate," a report upon the patient as a "life"—a report which, unknowing to the patient, can be 'used as evidence against him' when he is due to renew his policy, or, possibly, if he should seek a "life insurance." The certificate "is, of course, 'to be given at assured's expense'." The claimant, a healthy young adult, has had an influenza illness of moderate severity which has confined him to bed for a week and which will probably keep him from his work as a farmer for another week or ten days. He is not suffering from any other disease. One would think that legitimately, those are the only facts that the company would need to have certified. But in the case of this company "it is very essential (so the form reads) 'that full particulars be given so that the Medical Officer of the Corporation may understand the exact nature and extent of the illness'." So, to cast light into this medical officer's darkness I am asked to certify at the outset the claimant's age, weight, and height. Yes, the weight and height of a patient ill in bed! Am I to presume that, if I should have a fulminating case of meningitis or pneumonia insured for sickness with this company, I am to cart along with me a portable weighing machine, get the patient out of bed on to it, weigh him, and also measure his height? If I do not do so, will the medical officer fail to understand "the exact nature and extent of the illness"? Then this medical certificate form proceeds to ask twenty-one questions in all about my patient ill with an ordinary epidemic "influenza" pyrexia. Is he of sober and temperate habits? Has he suffered from cardiac affection, tuberculosis, gout, rheumatism, or fits of any kind? Are the teeth sound and is there any pyorrhoea? Of course the most objectionable feature of all is that the doctor feels that he must fill in this form so that his patient shall not suffer the loss of the payments due to him under his policy. The company therefore can reckon that the form will be filled in—and that they will have a free report on the patient as a "life."

Experiments on Human Beings

Dr LOUISE FRASER (Dundee) writes. As one who has served abroad in both wars I cannot be accused of being a conscientious objector, having volunteered for service. May I suggest then that so-called "voluntary" medical experiments on conscientious objectors prisoners in jails, and so forth are not ethical? The practice differs in degree, but not in principle, from the German prison-camp experiments.

Obituary

C Y PEARSON, MD, FRCS

Charles Yelverton Pearson, emeritus professor of surgery of University College, Cork, died on May 13 at the age of 89. He had been on the staff of the College for fifty years when he retired in 1928.

Charles Pearson was born at Kilworth, Co. Cork, in 1857, and his early years were spent at Carrigaline where his father was medical officer. He entered Queen's College, Cork, at the age of 17 and spent a year in the Arts Faculty before changing over to medicine. He qualified in 1878 and was appointed senior demonstrator of anatomy. For six years he worked under the late Prof. J. J. Charles until in 1884 he was appointed professor of materia medica and lecturer in medical jurisprudence. He had already proceeded M.D., being awarded a gold medal, and he took the English F.R.C.S. in 1886. He had been appointed assistant surgeon to Cork North Charitable Infirmary a year previously and some years later he became the senior surgeon there. He was also on the staff of the County and City of Cork Victoria Hospital for Women and Children and of the Lying-in Hospital.

At this time he was medico-legal adviser to the Crown in criminal cases and in this capacity was involved in what became known as the "Coachford Poisoning Case" or the "Shandy Hall Case".

The wife of a doctor in Dripsey had died in peculiar circumstances, and it was Dr. Pearson's evidence that led finally to a conviction for arsenic poisoning at the Munster Assizes in 1887. By the time he was 40, Charles Pearson had become professor of surgery at Queen's College, a position he continued to hold until 1928, when the University conferred upon him the title of emeritus professor. He was a member of the council of the University and of the senate of the National University of Ireland. In 1916 he succeeded the late Sir Charles Ball as honorary surgeon to the King in Ireland.

One of his daughters by his second marriage is now a medical student. His two sons are Dr. Charles B. Pearson of Cork, and Mr. William Pearson, professor of surgery, Dublin University. The sympathy of all who knew him as a skilled surgeon and a charming and likeable man will go out to his widow, his sons, and his daughters.

Dr. ROBERT ARTHUR HEATLEY, chief medical officer of the Bombay, Baroda, and Central Indian Railway, died in St. George's Hospital, Bombay, on April 8 after a short illness. He was 49 years of age. Dr. Heatley, who qualified in Dublin in 1925, joined the railway staff in the following year and spent the greater part of his service at the Railway Hospital in Ajmer. He acted as chief medical officer on more than one occasion and was confirmed in that appointment in November, 1946. He was a distinguished freemason, an honorary life member of the St. John Ambulance Association, and a member of the managing body of the Indian Red Cross Society. He had been a member of the British Medical Association for over twenty years.

Dr. SAMUEL EDWIN ALBERT ACHESON died in Belfast on April 14. Dr. Acheson started life as a pharmaceutical chemist and qualified from Queen's College, Belfast, in 1910. For many years he represented the medical committee in the Council of the Pharmaceutical Society of Northern Ireland. Dr. Acheson joined the British Medical Association in 1911, was chairman of the Belfast Division in 1929-31, a member of the Insurance Acts Committee from 1930 to the time of his death, and of the National Formulary Subcommittee in 1933 and 1937-8. He represented his constituency at nine Annual Representative Meetings from 1930 to 1938.

T. E. H. writes: He was a many-sided man, outstanding in every way, big in stature and big in heart. He ranked high in the masonic order. He was a great churchman and a great family man and his passing is lamented.

Dr. ROBERT SANDERSON died on April 21 at the age of 91 at his home in Lancing where he had lived since he retired from practice in Brighton. His father was Canon Sanderson, head master of Lancing College for many years. Educated at Lancing, Oxford and the Westminster Hospital, Robert

Sanderson qualified in 1883 and went into general practice two years later, but he soon began to specialize in gynaecology and became surgeon to the Brighton and Hove Hospital for Women. He was the first surgeon in Brighton to do a caesarean section. He proved a good general surgeon in the 1914-18 war when he served as a captain, R.A.M.C. in the 2nd Eastern General Hospital and with the 55th General Hospital at Wimcreux. He was elected president of the Brighton and Sussex Medico-Chirurgical Society in 1899, president of the Sussex Branch of the British Medical Association in 1920, and chairman of the Brighton Division in 1921-2. When the Association met at Brighton in 1913 he held office as president of the Section of Gynaecology and Obstetrics.

H. N. F. writes: Robert Sanderson, a man of lovable character and remarkable attainment, retired from practice long enough ago to be almost unknown to the younger generation. His rich humanity and unfailing regard for his patients' welfare brought him the reward of trust and affection. At the Sussex and the Brighton hospitals no one surpassed him in judgment and obstetrical skill. He seldom operated outside strictly gynaecological limits in civil practice, but he served on the surgical side in the 1914-18 war. His energy belied his years, for he was already over 60 when he went to France. Notwithstanding this, he took his full share in all the hospital's activities, even kept wicket for the officers, and generally opened the batting with the Irish padre, their combined ages being 110! Sanderson's charm and his many-sided interests made him a delightful companion. He was a scholar of distinction, an artist and a musician of wide culture. One would like to dwell on his love of all sports, his sympathy with all young things and their aspirations, his ideally happy home and family, his calm and courageous acceptance of the inevitable when he realized that his days were numbered. His blithe and gay spirit remained with him to the end and he leaves a memory of high ideals, faithful service, and golden friendships.

ALAN GORDON ADRAIN died at the age of 47 in Durban on April 28 after a short illness. In 1928 he took the conjoint qualification as a student of St. Mary's Hospital and then became casualty officer at the Royal Northern Hospital. He spent all his clinical life in Northern Natal, first at Felixton and later at Stanger, where he was senior medical officer to the Hulett sugar estates. Adrain served throughout the recent war and was demobilized with the rank of Surgeon Lieutenant-Commander, S.A.N.F. He served afloat for a number of years and then returned to the Durban H.Q. at Tribune House as naval medical liaison and transport officer. He leaves a widow and two children.

Dr. ERNEST JERMYN HYNES died at the City Hospital, Plymouth, on April 29. He studied medicine at the London Hospital, obtaining the conjoint diploma in 1896, the D.P.H. in 1901, and the F.R.C.S. in 1905. He was in general practice at Leigh-on-Sea for some years after qualifying and then in the Isle of Skye, where he practised for five years before joining the public health department in Huddersfield on his appointment as resident medical superintendent of the Infectious Disease and Smallpox Hospital. He returned to general practice at Grassington-in-Wharfedale for a period of eight years, and during the first world war was a captain, R.A.M.C., serving at the Stoke Military Hospital, Devonport. In 1919 he joined the staff of the Plymouth public health department as superintendent of the City Isolation Hospital and venereal diseases medical officer, remaining in this appointment until he retired in 1936. Once again he took up general practice, this time in Plymouth, and he was working to within a few weeks of his death.

D. F. J. writes: Dr. Hynes was a remarkable man with a phenomenal knowledge of clinical medicine. Although possessing a surgical qualification, his whole interest was in pure medicine, not confined to his own specialty but covering the whole field. His advice was much sought after by his colleagues especially where their own relatives and families were concerned. To work with him was a privilege. His charm of manner, his tolerance and his kindness were proverbial, and he never tired of imparting in characteristically modest fashion his great knowledge to his juniors. He devoted his whole life to his work and was ever ready to help all those in distress. He never lost his temper even under the most trying circumstances, but latterly even his calm temperament was at times disturbed by the spate of forms and certificates which fall to the lot of the unfortunate practitioner of medicine. He disliked all official documents. Apart from his wholehearted devotion to medicine, he was a pioneer motor-cyclist and motorist and a keen fisherman and photographer. He had an amazing know-

edge of birds and animals. We in Plymouth shall miss him, or he was a favourite with us all, a gentleman, and a great doctor.

Dr JOHN ROBINSON HARPER died in Barnstaple on April 30 at the age of 80. The eldest child of a family of thirteen his youth was spent in Barnstaple, where his father, Dr Joseph Harper, had been in practice for many years. He was educated at Blundell's School and later at St Thomas's Hospital, where he qualified in 1890. Dr Harper was house-surgeon and resident accoucheur at St Thomas's before joining his father in general practice. For many years he was a keen Territorial, serving as surgeon major in the North Devon Hussars. During the first world war he was twice mentioned in dispatches, and received the CBE and the Order of Avis (Portugal) as well as the Territorial Decoration. In 1918 he commanded the 14th Stationary Hospital in France. After the war he was for many years honorary surgeon to the North Devon Infirmary and was on the consultant staff of that hospital when he died. He had been mayor of Barnstaple in 1911, and up to this date had filled the post of medical officer of health to the borough. After his mayoralty he continued to be M.O.H. to the rural district of Barnstaple, and in this capacity was responsible for much of the A.R.P. work during the second world war. As a member of the Devon county council, and later as county alderman, he was on the public health committee, and was chairman of the mental deficiency committee. Dr Harper filled many other public posts with distinction. He had been a J.P. for many years and he was an active member of the British Medical Association for over forty years.

task of supervision of casualty and health services in his district. This devotion to duty lasted as long as life, and he carried out certain important official acts the night before his death. He was a man of high character and ability, tireless industry, and undaunted courage.—F.W.

Dr CHARLES GORDON GIBSON died on May 4 at the age of 83 at his home in Launceston, where he had been actively engaged in practice up to the time of his retirement in 1941. Dr Gibson qualified M.B., C.M. at Edinburgh in 1889. After serving as resident physician at Edinburgh Infirmary, and later as assistant medical officer at Kinross County Asylum, he came to Launceston in 1891. During the fifty years spent in practice he saw many changes. In the early days he used to travel by horseback to see his patients. His life was devoted to the practice of medicine, and night or day his patients came first. He possessed great clinical acumen and judgment and was greatly beloved. Apart from his professional abilities he was a man of great culture—a competent botanist, a keen astronomer, and a lover of the poets. Fittingly enough, Burns was his favourite, and he always retained a great love of his native Scotland. It was my privilege to be closely associated with him for some years, and I believe he was incapable of an unworthy or unkind thought or deed. At his passing many will remember with gratitude their contact with him.—R.E.A.

Medico-Legal

FAILURE OF A NATURE CURE

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

The deputy coroner for West Cumberland, Mr W. H. Bayliff, held an inquest on March 14th into the death of a boy of 13 who was found at necropsy to be emaciated, with gross distension of the abdomen, prolapse of the rectum, general peritonitis, and chronic obstruction of the bowel due to intussusception.

Dr T. F. Kirkpatrick, of Keswick, said in evidence that he had seen the boy first on Feb. 25, two days before his death. The father told him that the boy had been taken suddenly ill about the middle of December with severe sickness and diarrhoea, probably due to ice-cream. A few days later the lower part of the bowel had protruded slightly and gone back spontaneously, but afterwards it had protruded again to a greater extent and had remained prolapsed. On Dec. 28 the father had telephoned to a "naturopath" of Ayr, Mr J. B. S. Jay, who had seen the boy twice and had afterwards conducted treatment by telephone, prescribing homeopathic remedies. Until Feb. 18 the boy's bowels had moved spontaneously, but after that date there was no motion and he had taken nothing but sips of water. The doctor judged that the boy had probably developed a subacute obstruction at the beginning of his illness and that it had become complete on Feb. 18. He explained the gravity of the situation to the parents and said that surgery might have succeeded earlier but the boy was not now fit for it. They would not allow a consultant to be called, and asked him to communicate with Mr Jay. He declined to do so, as it would have served no useful purpose. They refused his suggestion of removal to hospital. Next day he called again and found the boy's condition worse. The parents then agreed that he should go to hospital provided that no surgical treatment was given. After the boy's admission he had prescribed "nepenthe" to relieve pain. The boy had died next day. The conditions at home had been moderately good, but a patient in such a serious state should have had professional nursing attention. The parents had appeared to be anxious and in an agitated state. He had gathered that they had had "naturopathic" treatment for seventeen years, and that this was largely based on diet. Religion had not been mentioned. If the boy had received medical treatment in the early stages he would very probably have recovered. Cross-examined by counsel for the parents he said their belief in "naturopathy" seemed genuine. He agreed that many patients were restored as much by warmth and rest as by orthodox medical treatment, and that in many

Dr JOHN WILSON MILLER died on May 2 at his home in Lewisham at the age of 62. A student of Glasgow University, Dr Miller qualified M.B., Ch.B. in 1907, and obtained the diploma in public health in 1910. After service in many Glasgow hospitals he was appointed in 1913 senior assistant medical officer of health and tuberculosis officer for the County of Lanark, a post he held for five years except for one year's absence on military service as a lieutenant in the R.A.M.C. Dr Miller also acted as medical officer of health for the Burgh of Hamilton for a period of fourteen months. In 1918 he became deputy medical officer of health for the metropolitan borough of Lewisham and he had been M.O.H. there from 1937 until failing health made him retire in 1946. Dr Miller had been a member of the British Medical Association since 1911 and was chairman of the Lewisham Division for the years 1928-9 and 1936-7. In his early days at Lewisham he was the first medical officer in charge of the first municipal maternity home in the metropolitan area. Many Lewisham mothers still remember with gratitude his sympathetic and efficient care. During the ten years he was in charge no maternal death occurred in the maternity home at Rushey Green. Later as medical officer of health he launched in 1930 the "home help scheme," now recognized as one of the largest and most successful in the country. In 1935, largely through Dr Miller's efforts, a general practitioners scheme for the immunization of children against diphtheria was brought into being and most successfully developed. A year later the first health centre in the borough was erected by the council and a modern tuberculosis dispensary built. During the war years the strain and responsibility of organizing and maintaining an extensive civil defence casualty service, which functioned smoothly and efficiently, contributed very materially to his breakdown. Dr Miller had a subtle sense of humour and he was always courteous, modest, and considerate towards those who worked for and with him. He was a much loved chief and colleague.

WALTER WINGFIELD NUTTALL of Folkestone died on May 4 at the age of 80. Dr Nuttall was a student of St Bartholomew's Hospital. He qualified in 1892, and proceeded M.D. in 1908. He had retired from general practice some years before the outbreak of war but he placed his services at the disposal of the War Office in September, 1939. In May, 1941, he accepted the position of medical officer of health for a wide district in East Kent. Although at the time of his appointment he was over 74 years of age, he immediately infused into his work a vigour and enthusiasm that earned for him the appreciation, and indeed the admiration, of his employing authorities. He re-organized the casualty services and ranged far and wide into the villages and hamlets of his scattered district. Approximately 100% of the children in his area were immunized against diphtheria by him personally. Dr Nuttall was appointed a magistrate for the borough of Folkestone thirty years ago. Highly esteemed by his colleagues on the bench and deeply interested in the work, he relinquished it in 1940 so as to be able to concentrate all his strength and energy on the essential

'naturopaths' must seem successful because they kept their patients in bed and warm. The success of early surgical treatment would have depended on a correct diagnosis. The boy had had a convulsion during his first examination, and he had suggested the possibility of meningitis, but the parents would not allow lumbar puncture. In answer to Mr Jay, he said that surgical treatment would probably have availed during the first few days after the prolapse appeared.

The pathologist Dr J S Foulds of Carlisle Infirmary, agreed and added that it would have been effective up to the period when the boy developed acute obstruction. If other advice had been obtained at the beginning the question of operation need not have arisen. He had not examined the brain. Questioned by Mr Jay, he said that such a prolapse, once reduced, might recur if the diarrhoea continued, but not if it were cured.

After a warning by the coroner Mr Jay decided not to give evidence, as also did the parents on legal advice. The coroner, summing up to the jury, said that as a matter of law the parents owed the boy the duty of providing him with food, clothing, and, if necessary, medical attention. Parents had in some cases been convicted of manslaughter for failing to call in medical aid for their children, but not every such failure amounted to manslaughter: there must be a breach of duty so gross as to amount to sheer criminal recklessness whether the child died or lived. Where a person, whether a qualified medical practitioner or not, held himself out as having skill in dealing with disease and undertook the care of a sick person, he owed a duty to the patient. The coroner pointed out that the parents had not neglected to get any treatment at all; mistakenly, the jury might think, they had brought in treatment of a sort, and had been very distressed at the boy's illness. They had called in Dr Kirkpatrick at the finish, though unfortunately too late. There was no suggestion that any treatment by Mr Jay had contributed to the boy's death; it was a case of lack of treatment appropriate to the particular condition.

The jury returned a verdict of death from natural causes, a contributory factor being the reluctance of the parents to provide earlier medical attention.

Dr Kirkpatrick's conduct stands as a model for other practitioners faced with the same sort of difficulty. The cases in which any useful purpose could be served by the medical practitioner called in making contact with an unqualified person must be extremely rare.

The Financial Board offer no objection to the contained in this Report.

UNIVERSITY OF CAMBRIDGE

The *Cambridge University Reporter* dated May 13 contains a report of the General Board on the establishment of certain additional posts in the Faculty of Medicine and on the further development of the School of Clinical Research and Postgraduate Teaching. The report, which occupies 3½ pages of the *Reporter* is the result of representations made by the Board of the Faculty of Medicine earlier in the year and concludes with the following recommendations to the University.

I That a Readership in Human Ecology be established from Oct 1, 1947 that the pensionable stipend of the person appointed to this post be £950 a year or £700 a year should he be a Fellow with dividend, and that from the same date the following be added to the Regulations for Readerships held under the Statutes of 1926 (*Ordinances* p 566) *Medicine Human Ecology*—The Reader shall not be a tutor, assistant tutor, bursar or assistant bursar and shall not give instruction on behalf of a college or colleges for more than six hours a week.

II That the head of the Department of Medicine be authorized to appoint, subject to the approval of the Faculty Board of Medicine, a senior health service officer, a junior health-service officer, and a statistician to the Department of Medicine, with tenure not exceeding three years in the first instance, and that the stipends of these health service officers and of the statistician be determined, subject to the approval of the Financial Board, by the General Board after consultation with the Faculty Board of Medicine.

III That the health service officers and the statistician to the Department of Medicine be recognized as officers of one of the departments of the Medical School for the purposes of the arrangement with Addenbrooke's Hospital (*Reporter* p 238).

Comprehensive Anti-anæmic Therapy

'VENTRON'

CAPSULES

In many instances of iron-deficient anaemia, especially that associated with nutritional inadequacy, there may be a lack of blood-forming elements other than iron. Consequently it is often advantageous to supplement iron therapy by giving the erythrocyte-stimulating factor in the form of desiccated gastric tissue together with vitamins B₁₂ and B₆ as general aids to nutrition.

Ventriculin is a stable anti-anæmic substance derived from gastric tissue and is a potent erythrogenic stimulant inducing active hematopoiesis with rapid elevation of the red blood cell count.

A combination of Ventriculin with vitamins B₁₂ and B₆ and ferrous sulphate is available under the name 'Ventron' in bottles of 50 and 1000 capsules.

invented by a Doctor . . .

TAMPAX, first introduced in 1934, was the direct adaptation by a practising Doctor of the principle of the surgical tampon to the absorption of the menstrual flow. As such, it received the approval of the medical profession not only for its alleviation of mental stress and physical discomfort but for its hygiene and absolute safety—ensured by the Tampax patent stitching process which

positively prevents disintegration. Today that approval is world-wide. Tampax is recognised as both the pioneer and the best form of sanitary protection worn internally. If you are not receiving copies of the new series of medical leaflets now being despatched, or require a sample packet of Tampax, please write to Medical Inquiries, Tampax Ltd, 110 Jermyn St, London, S W 1

Tampax may consider its use overruled by Physicians for use by married women during normal menstruation. Its use by unmarried girls should not be advocated when the size of the hymenal aperture would cause difficulty in insertion and withdrawal.

Sanitary Protection

TAMPAX

Medical Notes in Parliament

The National Health Service (Scotland) Act received the Royal Assent on May 21. Previously, on May 20, the House of Commons had agreed to the amendments made by the Lords in this measure.

THE NATION'S FOOD

LORD CHERWELL in the House of Lords on May 22, asked what food was available to make up to 2,900 calories a day the domestic rations, which with the domestic entitlement of eight points per week had been stated by the Government spokesman in the House of Commons to amount to 1,600 calories a day. Lord Addison had stated that 2,900 calories a day were obtainable by persons not using restaurants and canteens. He was sure Lord Addison was anxious that any trace of unfairness toward a member of his profession should be put right. Lord Addison had complained that the figures given by Dr Bicknell in the *Medical Press* were incorrect by about 30%. The issue was whether Dr Bicknell was right in stating that the amount to be derived from unrationed foods, excluding restaurant meals, was about 500 calories a day, bringing the total up to 2,100 calories, or Lord Addison, when he stated that the normal man or woman, with access to restaurant or canteen could bring the total up to 2,500. According to the Minister of Food, his Department's *Dietary Food Survey* showed that the food eaten in the home in December, 1945 was equal to 2,390 calories. In November, 1946, it was 2,320 calories, in December 1946, 2,300 calories. No later figures had been published. The decline was lamentable and steady. Dr Bicknell's 2,100 calories was within 9% of the figure given by the Minister of Food. Lord Addison had protested against a statement by Dr Bicknell that the unemployed before the war were better fed than most of the nation to-day. Lord Chervell believed this to be broadly true. Ten years ago Sir William Crawford and Sir Herbert Broadley found that the diet of the two poorest social groups, those with incomes under £249 a year, fell short of the standards prescribed by the British Medical Association. But even in the lowest social group with an income of less than 12s 6d per head per week, the average calories were given as 2,335 per head per day, 35 calories above the Ministry of Food December figure for the normal consumer to day who had not access to restaurants, canteens, and the like. In 1934 Sir John Boyd Orr concluded that the poorest 10% of the population obtained 2,317 calories a day. These figures justified Dr Bicknell's statement that the unemployed before the war were better fed. Sir William Crawford's investigations showed that the poorest 15% of the population obtained 65% more meat, 80% more bacon, 46% more fats, and 90% more sugar than the rations allowed to-day. By the League of Nations standard the whole of this nation was to day on the poverty line. That a small percentage of the population might get slightly more food than formerly did not outweigh the fact that an overwhelming majority were getting much less.

LORD ROTHSCHILD said a satisfactory diet included other vital ingredients beside calories. In 1942 the combined United Kingdom, United States, and Canadian Consumption Levels Inquiry Committee concluded that the method used by the Ministry of Food in arriving at the figure of 2,900 was the best available. They concluded that an attempt to weight the statistics would increase the risk of error. The method by which the figure of 2,900 had been reached in 1947 was identical to that used in the pre war period to get similar data.

Dietary Changes

LORD ADDISON said the figure of 2,900 calories was arrived at by dividing the total quantity of food going into consumption by the total population. The comparable figure for the pre-war period, ascertained in the same way, was 3,000 calories. The total consumption of meat was to-day about 9% less than pre-war. Fats were down by 29%, sugar by 26% and eggs by 14%. Consumption of dairy products, especially milk, was up by 30%. Fresh fish had increased by 28% and flour by 10%. Consumption of potatoes had increased by 64%. While the diet had become duller it approximated more closely to the nutritional foundation on which it should be based—dairy produce, vegetables and high-extraction bread. The average of 2,900 calories covered not only straight rations and points rations but also differential rations for heavy manual workers, unrationed foods, welfare foods for children and so on. The "straight" basic rations gave 1,400 calories to the ordinary adult and the points rations another 200 calories. This allowed

nothing for bonus issues of sugar and jams or for manufactured products such as meat pies and sausages. It did not cover the sweets ration. As extra sources of food, some 164,000 catering establishments provided some 59,000,000 main meals weekly. The requirements of the people as a whole were being adequately met. There was evidence that the classes which before the war suffered from malnutrition were on the whole, better fed to-day. Lord Addison remarked that he did not withdraw one word which he had previously said. The statement attributed to "this man" that England was dying of starvation was a falsity, sloppy, inaccurate, and altogether mischievous.

LORD WOOLTON said the writer of the article was a medical scientific authority higher than any other quoted. He had used the phrase 'dying of starvation' in a strictly technical sense and it was true. The nation was, in fact, starving for fats.

LORD CHERWELL pointed out that to get 1,300 calories from fish the consumer would have to eat 100 oz., or from potatoes, 51 lb., or from cabbage over 200 oz. A total of 59,000,000 main meals per week served in canteens and restaurants was only 1½ meals per head of the population per week. He thought the additional consumption of milk compared with before the war was likely to be only 20%, not an increase of 144% as estimated by Mr Strachey or of 30% as Lord Addison had said. If there was enough bread to produce 90 oz a week why was the ration only 63 oz?

The debate then closed.

Food Comparisons

MR STRACHEY, in answer to Mr Spence on May 12, said the number of calories available to civilian consumers per head per day in the United Kingdom in 1946 was 2,890—not, as had been erroneously stated, 2,100. The consumption of some individual foods in 1946 expressed as a percentage of their pre-war consumption was as follows: liquid milk 144%, eggs (shell, dried, and liquid) 87%, flour and grain products 115%, all vegetables 110%, tea 96%, oils and fats (excluding butter) 105%, butter 44%, bacon 55%, all other meats 93%, fish 120%, sugar (including sugar in all home-produced manufactured foods) 72%, potatoes 161%. The nutrient intake for 1946 compared with pre-war, showed about 4% less calories, 12½% more total protein but 3% less animal protein, 14% less fat, and about the same carbohydrate. This not very dissimilar quantity of food was in 1946 far more equitably distributed among the population than it used to be before the war. The quantity and quality of food which could be bought by large sections of our people before the war were far too low. The Ministry of Food would need to raise them substantially and as soon as possible in order to achieve a really satisfactory national diet.

MR STRACHEY, on May 12, also furnished the following table

Estimated Average Supplies Moving Into Civilian Consumption in the United Kingdom in 1946

	Calories	Nutrients per head per day
		2,890
Protein—animal		44.1 gm
—vegetable		46.0 "
—total		90.1 "
Fat		112.0 "
Carbohydrate		381.1 "
Calcium		1,043 mg
Iron		17.2 "
Vitamin A		3,738 IU
Ascorbic acid		107.5 mg
Thiamin		1.88 "
Riboflavin		2.00 "
Niacin		17.3 "

**Notification of VD*—MR WESTWOOD told Sir Thomas Moore on May 6 that he was not satisfied that making venereal diseases compulsorily notifiable in Scotland would help in eradicating them. The question had been carefully considered from time to time, and so far as Scotland was concerned the balance of opinion had been that compulsory notification might hinder the campaign which the doctors, the Government, and the local authorities waged against these diseases. Sir Thomas Moore spoke of the danger of infection to young children with an infected person in charge of them and gave notice that he would raise the subject on the adjournment.

Category E—Approximately 109,000 men were discharged from the Army between September, 1939, and VJ Day on psychiatric grounds, 288,000 on account of other diseases and accidental injuries, 26,000 on account of injuries due to enemy action.

Hearing Aids—The Minister of Supply has already placed contracts for the manufacture of aural aids. He hopes that enough will be available to make a start with distribution when the National Health Service begins. They will then be available without charge to patients for whom they are prescribed.

No 19

EPIDEMIOLOGICAL NOTES

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended May 10

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland

Figures of Births and Deaths and of Deaths recorded under each infectious disease are for (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland

A dash — denotes no cases a blank space denotes disease not notifiable or no return available.

Disease	1947					1946 (Corresponding Week)

Smallpox

Contacts are still under surveillance in connexion with the outbreaks of smallpox at Barnsley and Sheffield West Riding and at Bilston and Cosley Staffordshire

Barnsley—The source of infection at Barnsley has not yet been determined with certainty but a man who had been exposed to smallpox in a common lodging house at Scunthorpe and was at the time re-vaccinated successfully (April 5) arrived at the Barnsley lodging house on the evening of April 30. Among innumerable marks of recent scabies, and trauma on his body was one pock mark suggestive of variola six or more weeks ago and half a dozen nondescript scars which might have been modified smallpox. Attempts to culture variola virus from him have failed. He has been notified as smallpox and is in hospital. In addition to the man removed from Bermondsey on May 16 there are now 5 cases in the first generation arising at Barnsley. 3 of these were mentioned last week (May 24 p. 745) the remaining 2 both males aged 68 and 70 developed rashes on May 17 and 19. It is doubtful whether the man from Scunthorpe could have infected the earliest case in this generation who is recorded as having had a pustulo-vesicular rash when he was admitted to a general ward at St Helen's Hospital Barnsley, on May 13. He remained there until he was removed to the smallpox hospital on May 16. There were 93 men, women and children sleeping in the Barnsley lodging-house when the disease was detected there on May 16. Of these 5 absconded but only two (Elizabeth Fenton and Lewis Stewart) remained untraced. Assuming that the period of infection at Barnsley began about April 26 several contacts had left before surveillance started and are still untraced. One of them, a man named Thomas Durlin was also a contact with smallpox at Grimby. Any news concerning his whereabouts should be communicated immediately to Whitehall 4300 extension 145. The disease at Barnsley is variola major of a severe type. 2 of the patients have died.

Sheffield—The father and aunt of the original case have been removed to hospital. The father successfully vaccinated for the first time on May 5, sickened on May 13 and developed a markedly modified smallpox rash on May 18. The aunt is at present a suspect only.

Bilston—A new case has been removed to hospital—an unvaccinated child aged 11 with onset on May 16 and a rash which appeared on May 19. She lived in a house near that occupied by the cases removed in April.

Cosley—An unvaccinated kitchen maid at Moxley Infectious Diseases Hospital became ill while at her home in Cosley on May 13. A severe confluent eruption appeared on May 15.

Discussion of Table

In England and Wales infectious diseases were more prevalent. Increases in the number of notifications were reported for measles 1 692, whooping cough 189, scarlet fever 129, acute pneumonia 45, and cerebrospinal fever 22. Dysentery with 12 fewer cases was the only disease to show a fall in incidence during the week.

The rise in the notifications of measles was fairly general but large increases were recorded from only a few counties notably Yorkshire West Riding 627, Staffordshire 246, London 136 and Middlesex 87. The increase in cases of whooping cough was mainly confined to the neighbourhood of London the largest increases were Middlesex 69, London 50 and Kent 37. The only change of any size in the local trends of scarlet fever was a rise of 57 in Lancashire. Notifications of diphtheria increased by 9 in Lancashire and by 8 in London. Lancashire had 72 cases of dysentery almost two thirds of the total for the country (Prestwick M.B. 40, Liverpool C.B. 18, St Helens C.B. 10).

In Scotland infectious diseases, in contrast to the trend in England and Wales tended to decrease. The falls in notifications included measles 73 and whooping cough 30 while the only increases of note were acute primary pneumonia 17 and diphtheria 15.

In Eire increases were reported for diarrhoea and enteritis 11, measles 7 and diphtheria 6. There was a decrease of 15 in the notifications of whooping cough.

In Northern Ireland the only changes were increases in the notifications of measles 8 and diphtheria 5.

Week Ending May 17

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1 028, whooping cough 2 120, diphtheria 243, measles 12 678, acute pneumonia 578, cerebrospinal fever 57, dysentery 65, acute poliomyelitis 11, paratyphoid 3, typhoid 9, smallpox 12.

Medical News

The Chelsea Clinical Society, one of the youngest medical societies in London, was founded in 1897 and its first President was Dr J Foster Palmer. It originally consisted of only 15 members, all of them resident in the south-west district of London. They met together once a month in a dispensary in Chelsea and at these informal meetings it was a tradition that whisky should be provided. Membership grew until in 1909 there were 126 members, a year later the Society held its meetings in the students' clubroom of St George's Hospital. After 1922 the business of the Society was conducted at dinner meetings, and membership rose to 230. The President's Jewel was presented by Dr T W Parkinson, later Sir Thomas Parkinson, a Silver Bell was presented by Dr Gordon Lane, and is used by the President to call to order any member thought to have spoken too long. The President has another disciplinary instrument in the shape of an Ivory Gavel and Block. The Chelsea Clinical Society celebrated its Jubilee at a dinner last week presided over by the President of the Society, Dr Ronald Jarman. The Earl of Clarendon, who was the principal guest of the evening, paid a personal tribute to the medical profession when proposing the health of the Chelsea Clinical Society. He congratulated the Society on its present prosperity and mentioned the fact that its membership was now over 200. In response, Dr Jarman thanked the Presidents of the various medical societies and especially the Presidents of the Royal Colleges for rallying round the Chelsea Clinical Society on the occasion of its Jubilee. Sir Cecil Wakeley proposed the toast of the guests and Mr Russell Vick, K C and Sir Hugh Lett, Bt, suitably replied.

A science meeting of the Colour Group of the Physical Society will be held at the Lighting Service Bureau Electric Lamp Manufacturers Association, 2, Savoy Hill, London, W C on Wednesday, June 4, at 3.30 p.m. when Mr H G W Harding will read a paper on "The Colour Temperature of Light Sources".

Owing to indisposition Sir John Fraser will be unable to be present at the first post-war dinner of the Edinburgh University Club of London on June 5 announced in this column last week at p. 749. Sir Henry Wade will reply for the University. Among other acceptances are Admiral Lord Cunningham and Field-Marshal Lord Wilson. The dress for the evening will be tails or dinner jackets. Any member who has not yet received notice should write the honorary secretary at 12, Wimpole Street, London, W 1.

A meeting of the Faculty of Homoeopathy will be held at the London Homoeopathic Hospital, Great Ormond Street, London, W C, on Thursday June 5, at 5 p.m. when Dr J D Kenyon will read a paper entitled "Comments on the Homoeopathic Treatment of Diabetes".

Mr L H Savin will deliver a lecture on "Cataract" before the Whipp's Cross Hospital Medical Society on Friday, June 6 at 8.30 p.m.

The annual general meeting of the Association of Orthopaedic Physiotherapists will be held on Saturday June 7, at 2.30 p.m., at the London School of Hygiene and Tropical Medicine, Keppel Street, W C, when Brig R J Furlong, FRCS, will speak on "The Spine and its Physical Treatment".

Prof H E Sigerist will retire in June from the Chair of Medical History and the Directorship of the Institute of the History of Medicine at Johns Hopkins University, Baltimore. After studying at Zurich, University College, London, and Munich, and gaining his M.D. Zurich in 1917, Prof Sigerist was appointed lecturer on the history of medicine at Zurich and later professor of that subject at Leipzig University. He went to Johns Hopkins University in 1931. Prof Sigerist intends to settle in Switzerland and write a history of medicine throughout civilization.

The summer week-end course arranged by the Empire Rheumatism Council (Tavistock House (North), Tavistock Square, London, W C) will be held at the Apothecaries Hall, Blackfriars Lane, Queen Victoria Street, London, E C, on Friday, Saturday, and Sunday, June 13, 14 and 15. On June 13 at 4.30 p.m., Sir Adolphe Abrahams will deliver the inaugural lecture and at 5.30 p.m. Dr Ernest Fletcher will speak on Arthritis. The programme for June 14 is as follows: 10 a.m. Dr R E Bonham Carter "Juvenile Rheumatism and Still's Disease"; 11.15 a.m. Dr G D Kersley, "Spondylitis"; 2 p.m. Dr George Graham, "Gout"; 3 p.m. Dr W S C Copeman, "Non-articular Rheumatism and Scurvy"; and 4.30 p.m. Dr Oswald Savage, "Differential Diagnosis of Arthritis". On June 15, at 10 a.m., Dr F S Cooksey will speak on "Physical Treatment in the Rheumatic Diseases" and at 11.15 a.m. Mr W D Collart will discuss "Orthopaedic Aspects of the Rheumatic Diseases". The fee for the course is £1 1s and the number of entries is limited to 50. Applications to join should be sent to the General Secretary of the Council at the above address.

The Société des Médecins Inspecteurs des Ecoles de la Seine and the Société Française d'Hygiène Scolaire have arranged a conference on health in the school and the university to be held from June 23 to 29 at the Faculty of Medicine, University of Paris under the patronage of the French Ministries of Education and Health. Plans are being made for visits during the conference to schools, dental care institutes and centres of educational psychology. Visitors will also be able to attend physical education demonstrations organized by the conference of the League of Physical Education, which will take place during the same dates as the health conference. A joint meeting of the two conferences will be held at the Sorbonne. Those wishing to attend should write as soon as possible to Dr Astre (Direction de l'Hygiène Scolaire, 5, Rue Auguste Vaequerio, Paris, VIII^e) from whom full particulars as to fees, etc., can be obtained.

Dr Jerzy Chorobski, lecturer in neurosurgery in the University of Warsaw, has arrived on a visit to this country under the auspices of the British Council. He is visiting hospitals and medical institutions in London, Manchester, Edinburgh, Oxford and Cambridge. Before the war Dr Chorobski held a Rockefeller Foundation Fellowship and worked in neurosurgical centres in London and in America.

Dr G T Badenski, professor of pathology in the University of Temisoara, Rumania, who has been doing research work on virus diseases including influenza, has arrived on a visit to this country, under the auspices of the British Council. He will be mainly engaged in research studies at the Malaria Laboratory, Horton Hospital, Epsom, but will also visit universities, research institutions and hospitals in London, Liverpool, Manchester, and Sheffield.

Sir Alexander Fleming has been awarded the American Order of the Purple Heart for his work on penicillin, which saved so many lives during the war.

Dr Kenneth Mellanby, reader in medical entomology in the University of London, has been appointed Principal Designate of the University College which it is proposed to establish in Nigeria. Dr Mellanby, who was born in 1903 and educated at Barnard Castle School and King's College, Cambridge, has carried out research work at the London School of Tropical Medicine and Hygiene and in East Africa. In 1945 he was awarded the OBE for distinguished services in connexion with the preservation of the health of our troops in South East Asia. Recently Dr Mellanby went over to Nuremberg to report on the war crimes trials in which German medical men were involved. His account of "Medical Experiments on Human Beings in Concentration Camps in Nazi Germany" appeared in our issue of January 25, 1947, at p. 148.

The Royal College of Obstetricians and Gynaecologists, which was founded as a company without share capital eighteen years ago, has now received its Royal Charter dated from March 21.

The Royal National Orthopaedic Hospital at Stanmore has recently instituted a 24 hour accident service. Accidents of all types, particularly those of industrial origin, are being dealt with. This new development is part of the hospital's policy in widening its scope and function so as to provide full training for post-graduates in all branches of orthopaedic surgery. The telephone number of the hospital is GRimsdyke 1894.

Prof R E Lane, of Manchester University, has been appointed a member of a committee set up by the Minister of National Insurance under the chairmanship of Judge Edgar T Dale to review the policy adopted in scheduling industrial diseases under the Workmen's Compensation Acts and to advise on the principles that should govern the selection of diseases for insurance under the National Insurance (Industrial Injuries) Act. Those interested are invited to submit evidence in writing to the Secretary, Mr F K Forrester, Ministry of National Insurance, 6, Curzon Street, London W 1.

President Truman has asked Congress to give immediate attention to the enactment of a national health and disability insurance scheme, which should include adequate public health services, additional medical research and medical education, more hospitals, insurance against the costs of medical care and protection against loss of earnings during illness.

The Freedom of the Borough of Buxton was on May 30 conferred on Dr C W Buckley Alderman of the Borough.

Dr Frederick Reiss, formerly Professor of Dermatology at the National Medical College and St John's University Medical College, Shanghai, China and recently of Cornell Medical College, has been appointed Associate Clinical Professor in the Department of Dermatology and Syphilology, New York University College of Medicine.

Dr William Dyson, O.B.E., consultant to the Manchester Hospital for Skin Diseases, who died on Feb. 5, left £9,326. Sir Harry Linnington Martyn, K.C.V.O., late Surgeon Apothecary to H.M. Household at Windsor, who died on Jan. 7, left £10,110.

Any Questions ?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Treatment of Muscular Rheumatism

Q—A patient with muscular rheumatism or fibrositis of the shoulder has been treated with an autogenous vaccine consisting of non haemolytic streptococci and mixed staphylococci taken from a throat swab. Is there any rationale for this form of treatment, and is it worth while continuing it?

A—Vaccine treatment is rarely of any use in cases of this type, though sometimes a septic tonsil may be the cause. Cases have been reported of an acute periarthritis of the shoulder apparently infective and endemic or epidemic in some districts. They tend to clear up in a few weeks. Mild trauma is often responsible, especially in cases of occupational origin leading to irritation of the cords of the brachial plexus from tension of the scapula, often associated with a cervical rib or large transverse process. Thorough clinical investigation and x-ray examination are necessary to find the cause. Treatment of septic tonsils is called for, possibly tonsillectomy, local x-ray treatment has been strikingly effective in some cases. A sling should be worn to rest the muscles, infra red rays followed by light massage or ionization with histamine, or salicylates are other useful forms of treatment.

Penicillin for Hand Infections

Q—What is the indication for penicillin therapy in local staphylococcal infections of the hand? To what extent does it replace surgery? Should injections be started before or at the time of pus formation?

A—Penicillin therapy is indicated in every case of infection of the hand except the most trivial. This should be started at the earliest possible moment, as by this means many staphylococcal infections will be aborted and the dire streptococcal infections prevented. So serious are the after results (functionally, aesthetically, and economically) of hand infections—even those that at first sight appear minor—that too much stress cannot be laid on the prophylactic side of treatment, and in this respect penicillin provides an invaluable weapon. If hospital treatment is not indicated or possible (where intensive dosage can be provided) massive daily doses of about 250,000 units should be given parenterally until the local condition has resolved. If pus has actually formed (for example, pulp abscess) incision will still be necessary, but local penicillin dressings (powder or ointment) after the early post-operative effusion has settled will greatly expedite healing. It cannot, therefore, be said that penicillin therapy has entirely replaced surgery in hand infections, but it has, except in neglected cases, limited it to the drainage of local collections of pus and it has removed the dread of the dire sequelae.

Tuberculin Tests

Q—What is the technique of the Mantoux test? Is there any danger if an active focus is suspected and should precautions be taken? I should also like particulars of the patch test.

A—The Mantoux test consists in the introduction of a certain known quantity of tuberculin intradermally to determine hypersensitivity to tuberculo-protein. The technique of the test has been laid down in detail in the supplement to the Ministry of Health circular 166/45, dated Sept. 28, 1946. It is carried out by injecting intradermally, with a sterile tuberculin syringe and No. 29 needle, 0.1 ml of 1/10,000 solution of old tuberculin (OT) or 0.0002 mg of purified protein derivative (PPD). The injection is usually made on the flexor surface of the forearm after cleaning the area with alcohol. If no reaction is obtained after two hours a further injection is made of 0.1 ml of 1/1,000 solution of OT or 0.005 mg of PPD. If there is

still no reaction after a further lapse of 72 hours a third test is made with 0.1 ml of 1/100 OT. The reaction should be read 48 hours after the injection. A positive reaction is indicated by an area of swelling 5 mm or more in diameter. Any swelling less than 5 mm across or simple redness of the skin should be considered as negative. Except in very sensitive individuals, in whom it may produce a severe local reaction the test is harmless. No permanent disability has been known to occur, and in the large majority of instances the local reaction causes no discomfort. The main precautions consist in giving careful attention to technical details particularly with regard to sterility and the use of freshly prepared tuberculin.

The patch test is the determination of skin sensitivity to tuberculo-protein by the transtaneous method. The patch consists of a strip of adhesive tape on which is placed a square of filter paper saturated with OT. The test material, if kept in a cold dry place, will remain reliable for six months. It is important to see that the skin is thoroughly cleaned with ether or acetone before applying the test. In some definitely positive cases the result may not be readable until after five or six days, but usually a reaction is present in 72 hours in positive cases. The site of choice for the patch test is the skin area between the scapulae just right of the midline. This test is rather less sensitive than the Mantoux test but is useful in infants and small children, who may be frightened by the intradermal method. Occasionally in a sensitive patient the reaction is great and even vesiculation may occur. It may take two to three weeks to fade.

Acrocyanosis

Q—A healthy well built girl of 11 has had very marked but painless cyanosis and swelling of the hands and feet during the last four winters. There are no familial tendencies to the condition. What treatment do you suggest?

A—Acrocyanosis is not rare at this age and in this sex. The majority of girls suffering from this condition require no normal circulation in the skin of the extremities after puberty. Thus there is no indication for radical treatment at this age. The hands and feet should be kept warm with thick woollen gloves and stockings during the cold weather and the nutrition of the skin should be carefully preserved. If acrocyanosis persists when the patient has reached 19-20 years and is causing discomfort a full investigation is called for and sympathectomy might be considered.

Sterilization of Glass Syringes

Q—An article recently gave instructions for wrapping all glass syringes in kraft paper or cellophane before sterilizing in a hot air sterilizer or autoclave. I understand that cellophane is impervious to steam. How then is sterilization achieved by this method?

A—Wrapped all glass syringes should always, if possible be sterilized in a dry oven at 160°C for one hour. Kraft paper is somewhat more permeable by steam than cellophane and if a good vacuum is obtained in the autoclave steam will in any case get inside the wrapping between its layers. What is more serious is that steam cannot permeate the interior of the syringe itself, especially if this is lubricated with liquid paraffin. Autoclaving an assembled syringe is thus tantamount to sterilization by dry heat at the temperature employed—say 120°C. This is likely to destroy any but sporogenous organisms but cannot be regarded as a dependable method of absolute sterilization.

Induction by Drew Smith's Catheter

Q—Please describe in detail the technique for using the Drew Smith catheter in induction of labour.

A—With the patient in the lithotomy position the vulva, vagina, and cervix are cleansed and painted with an antiseptic solution. Two fingers of the left hand are then inserted into the vagina and the first finger is passed through the cervix. Previous dilatation of the cervix is usually unnecessary. The catheter, with the stylet withdrawn, is held in the right hand and its tip guided through the cervix along the finger of the other hand. It is passed between the membranes and the uterine wall behind the presenting foetal head. When the tip

is just above the curve of the foetal head and pointing forwards towards the foetal neck, the stylet is pushed in and the membranes punctured. The liquor flows back through the catheter, and at least 500 ml should be withdrawn to ensure the induction of labour. The catheter is then taken out and labour usually begins within forty-eight hours. Opinion is divided as to whether the patient should be given an anaesthetic. It is sometimes essential in primigravidae, and in a multiparous patient it has the advantage that it permits a more thorough cleansing of the vagina.

Ejaculatio Praecox

Q—What advice should be given to a healthy man aged 30 newly married who ejaculates prematurely? There is a previous history of masturbation.

A—Ejaculatio praecox is often said to be due to a man's being 'too keen', but in fact it is found to be of the same nature and to have the same motive as sexual impotence—namely, a subconscious unwillingness to have intercourse, which is therefore prevented by the premature ejaculation. This inhibition is often due to an early engendered fear of sex. Masturbation as such does not produce it, but in so far as masturbation is an expression of self-love it inhibits love for the partner and may therefore be an important factor. Apart from this, some boys are often threatened with the consequences of sex, which threat may remain subconsciously although it may be discarded consciously, while others are told that masturbation leads to impotence and other disorders and this may have a deterrent effect by suggestion. Early circumcision is in many cases the inhibiting factor, especially when it is regarded as a punishment for sex. Fortunately, if the matter is taken calmly, and love for the wife, in its true sense, is encouraged, leaving the sex side to take care of itself, the condition usually resolves in time. If not, analytical treatment to discover and get rid of the cause should be advised.

Receding Gums

Q—How can recession of the gums be prevented?

A—Recession of the gums with advancing years appears to be one of the penalties derived from civilized diet and disuse of and lack of friction on, the gums appear to make them more liable to infection with gradual loss of the supporting tissues. Treatment should aim at keeping up the tone of the gingival tissues by massage, with careful scaling and cauterization of pockets or gingivectomy in order to eliminate any sepsis.

Books on Psychology

Q—Can you recommend an elementary book on psychology?

A—Perhaps the best simple book on pure psychology is Woodworth's *Psychology*. If, however, an elementary knowledge of medical psychology is required the question is more difficult to answer, because there is such a variety of approaches and no textbook has been written. We should therefore suggest going to the source of modern psychopathology and reading Freud's *Papers on Hysteria* which shows how he came to discover the importance of conflict repression, and wish-fulfilment in the neuroses and then Freud's *Introductory Lectures on Psychoanalysis*. Later authorities—such as Jung's *Analytical Psychology*, Adler's *Neurotic Constitution*, McDougall's *Normal Psychology and Abnormal Psychology*—can be better understood when a start has been made on these.

Cystine Stones

Q—Large cystine stones were removed from the kidney of a girl aged 4. Stones are also present in the other kidney. It is said that cystine stones can be dissolved with suitable diet. Could you please supply full details of this treatment?

A—Cystinuria is due to a hereditary abnormality in metabolism and we know of no diet which will prevent the formation of cystine crystals in a patient who suffers from this condition. Nor are we aware of any method by which cystine stones can be dissolved after they have formed.

Letters and Notes

Penicillin Snuff for Colds and Sore Throats

Dr H F BARNARD (Beverley, E. Yorks) writes: Dr J F Buckmaster (April 5, p. 476) has drawn attention to his work showing that penicillin snuff 'materially shortened and mitigated the common cold by reducing secondary bacterial invasion'. Our experience at Beverley Emergency Hospital is in agreement with this, and competent opinion elsewhere has expressed the same view. It is not commonly realized that penicillin snuff is valuable in the treatment of sore throats (Meadley, R G S, and Barnard, H F, *Lancet* 1946 1 87). A dose of 1,000 units maintains an adequate bacteriostatic concentration in the pharynx for up to four hours. The film of snuff coated mucus is slowly swept back by the ciliated epithelium of the nose to the pharynx and posterior surface of the tongue. Involuntary swallowing movements then bring it forward to the fauces, and tracing this flow with methylene blue shows that the posterior pharynx in particular is reached. After thus demonstrating its possibilities a series of sore throats in R.A.F. personnel were treated in bed. Penicillin snuff was given to alternate cases, the others acting as controls. The snuff treated cases showed a shorter period of disability and more rapid clearance of pathogenic bacteria. Penicillin lozenges, gelatin pastilles as advocated by Drs A B MacGregor and D A Long (Feb. 1, p. 197) or chewing gum introduced by McIntosh, C F and Perryman, P W (*Pharm J* 1946, 157 354), are indicated in buccal infection. In conclusion I would like to draw attention to the simplicity of this four hourly snuff method of achieving prolonged antiseptic activity in the upper respiratory tract. A small piece of paper is folded obliquely and from this is tipped and sniffed into each nostril as much powder of penicillin in sulphathiazole, 10,000 units per gramme, as will stand in a 1 cm circle.

Cider and Rheumatism

Prof B T P BARKER (University of Bristol Agricultural and Horticultural Research Station, Long Ashton) writes: Under the heading 'Any Questions?' (April 12, p. 515) an inquiry was made as to the grounds, if any, for the current belief that cider drinkers do not suffer from rheumatism of the arthritis type. In the reply given it was stated that salicylic acid is often added to cider, some times in very large amount, and this may be the origin of the idea. To prevent any misconception and possible harm to the cider industry of this country I wish to point out that neither salicylic acid nor any preservative other than sulphur dioxide is permitted in this country for addition to ciders. The maximum quantity of sulphur dioxide allowable is 14 gr (0.9 g) per gallon—i.e., 200 parts per million or 0.02%. The regulation has now been in force for many years.

Treatment of Post herpetic Pain

Dr N N TERESHCHENKO (Wandsworth) writes: I am surprised that in your answer to the question on the treatment of post herpetic pain (April 26, p. 585) you do not mention parenteral liver extract injections. This method was first described in your *Journal* (1946 1 942, 2 38). I had the opportunity to use it twice, each time with a dramatic result, the pain disappearing within twelve hours.

Correction

In the paper entitled "Occupied Holland" by Dr Henriette A Lohr published in the *Journal* of April 19, we omitted her reference to the work on "hunger osteopathy" done by Dr Pompen, Dr Groen, Dr la Chapelle, and Dr Mercx. Dr Lohr's observations on this were taken, by permission, from a monograph by these authors which is now published in Holland, and she is anxious that the description of this new clinical entity should be properly attributed to the above named authors. Dr Lohr's paper as published in the *Journal* was a much abridged version of an address given last September to the London Association of the Medical Women's Federation.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. BRITISH MEDICAL JOURNAL

LONDON SATURDAY JUNE 7 1947

CENTENNIAL OF THE AMERICAN MEDICAL ASSOCIATION

BY

MORRIS FISHBEIN, M.D.

Editor Journal of the American Medical Association and Hygeia the Health Magazine

The first meeting of the American Medical Association took place in Philadelphia on May 5, 1847. The ideals and motivations that inspired its founders were a logical development of the thousands of years of tradition which have marked the medical profession through the centuries. The medical practice of 1847 in the United States more

closely resembled British medicine than that of any other European nation. Many of its greatest leaders had been schooled in British medical colleges. Indeed, Oliver Wendell Holmes, who served as chairman of the first committee on medical literature, felt that American medicine had followed far too closely its British pattern, and urged the creation in the United States of a distinctive medical literature.

Ideals and Patterns

The primary purpose of the American Medical Association was the advancement of medical education. In 1847 schools were mostly owned by groups of physicians who conducted these institutions as a means of enhancing their individual prestige and income. There were no definite standards. Little real progress was made in achieving this objective until shortly after the turn of the century. Up to 1880 the suggestion had been made many times that the American Medical Association be organized according to the pattern of the British Medical Association. However, the suggestion did not fall on fertile soil, and until 1900 the Association continued to be a representative body organized on a somewhat peculiar plan. There were representatives from the medical schools, from such State medical societies as had been organized, and also from other medical societies such as district and tri-State and specialistic

groups. A truly democratic organization was established with the reorganization in 1901, at which time representation was definitely limited to the individual States according to the number of members in the State medical society, and each of the scientific sections of the American Medical Association was permitted one

delegate in the representative body. In addition a delegate was assigned to each of the medical departments of the armed forces—the Army and the Navy—and also one to the U.S. Public Health Service. For many years attempts were made to obtain some representation for the Veterans Administration. Only following World War II, however, did the Congress of the United States establish the medical department of the Veterans Administration according to a plan resembling that of the medical departments of the Army and Navy; now the Veterans Administration will also be entitled to one representative.

This representative body, known as the House of Delegates of the American Medical Association, is the policy-making body. It determines the principles that govern organized medicine in the United States. All of the officers, employees, and other representatives of the American Medical Association are presumably bound in their official pronouncements to represent the policies established by the House of Delegates.

Nathan Smith Davis * Founder of the American Medical Association

Journal of the American Medical Association

For many years the American Medical Association met once each year and thereafter published a volume of *Transactions*, including the actions taken by the meeting and the scientific papers that were read. By the second decade, suggestions began to be made that the Association publish a periodical similar to that published by the British

Medical Association At one time Mr Ernest Hart, then editor of the *British Medical Journal*, was invited as guest and consulted frequently as to the principles governing such a publication Eventually in 1883 the *Journal of the American Medical Association* was established It did not attain great circulation nor prestige, nor was it able to earn much income for the American Medical Association until Dr George H. Simmons, an Englishman by birth and a citizen of the United States by adoption, became editor of the *Journal* in 1899 and subsequently the secretary and general manager To him also is given most of the credit for the plan of reorganization and growth of the Association that has taken place since 1900 As an outgrowth of the reorganization plan, the Association developed finally the concept of Fellowship A Fellow of the American Medical Association is a physician who is a member of a county and State medical society and who then applies for Fellowship in the American Medical Association and subscribes to the *Journal* To-day the circulation of the *Journal of the American Medical Association* is in excess of 133,000 weekly, and of its subscribers less than half are Fellows of the American Medical Association

Printing and Other Publications

When Dr George H. Simmons became editor, and general manager of the Association, he undertook promptly an expansion of its printing facilities During its first few years the *Journal* was printed by a private printer Shortly thereafter a typesetting machine was purchased, and from time to time the equipment was expanded so that to-day the Association employs about 350 employees in its printing department It has many flat-bed presses and four rotary presses one of which prints 96 pages in six forms and in two colours simultaneously The *Journal of the American Medical Association* and the special periodicals are all products of the Association's own printing plant The special periodicals were initiated in 1908 with the *Archives of Internal Medicine* Shortly thereafter came the *American Journal of Diseases of Children* The special periodicals now include

- Archives of Internal Medicine
- American Journal of Diseases of Children
- Archives of Neurology and Psychiatry
- Archives of Dermatology and Syphilology
- Archives of Surgery
- Archives of Otolaryngology
- Archives of Pathology
- Archives of Ophthalmology
- Occupational Medicine

Directory

Early in the 1900's also, the Association found it desirable to maintain its own file of all of the physicians licensed to practise in the United States and determined to publish a directory This directory has been regularly published every two years, except for the war periods, and represents one of the most valuable assets of the Association Indeed in both World War I and World War II the United States Government depended on the American Medical Association for recruitment of physicians to meet the needs of the armed forces The Association had, in fact, the only complete up-to-the-minute file of practising physicians available in the nation Indeed it is safe to say that few, if any, of the States had biographical files of their own physicians actually in practice Toward the end of World War II the Government developed a national roster of scientific and trained personnel, but even this effort has already fallen into desuetude

One more publication of the American Medical Association which represents an important contribution to the advancement of medical science is the *Quarterly Cumulative Index Medicus* The first complete index of the important medical literature of the world was the *Index Medicus*, founded by John Shaw Billings and continued by Robert Fletcher and Fielding H. Garrison When this fell on difficult times aid was given by the Carnegie Foundation, which eventu-

Dr George H. Simmons

ally withdrew its support Previous to that time the American Medical Association had undertaken the *Quarterly Cumulative Index*, which made no pretence beyond the indexing of 400 selected periodicals With the combination of the *Quarterly Cumulative Index* with the *Index Medicus* came the new publication, which now indexes more than 1,200 periodicals and which represents the most complete index of medical literature of the world thus far attempted Parenthetically, the annual loss in producing this publication has varied from \$30,000 to \$60,000

The Councils of the Association

When the Association found itself confronted with the problem of suitable controls over medical education and with the problem of regulating the advertising of proprietary medicines in its own pages, a pattern of development evolved which has become the usual technique to be followed in solving any of the many great problems that confront the organization For years there was a Committee on Medical Education which rendered annual reports In 1905 this committee was established as the Council on Medical Education with a full time secretary in the headquarters office This Council undertook to

examine the medical colleges and to establish a minimum standard of medical education. Colleges which met the standard were rated Class A, and others which failed in certain particulars were rated Class B. Those which were found completely inadequate were listed in Class C. Year after year the inspections continued and the ratings were published. There were 165 medical colleges in the United States in 1905. Less than 20% of these were rated Class A at that time. To-day there are 77 medical colleges in the United States, and all of them are Class A. There is one medical school in Class C. The improvement has occurred by elimination of the inadequate schools, the combination of several weaker schools into one strong institution, and the development of new medical schools as departments of great universities. The stimulus to improvement was simply annual publication of the facts to both the medical profession and the public.

Since the right to practise medicine in the United States must be obtained by licensure of a State Licensing Board, the Council on Medical Education also publishes each year the records of the graduates of the individual schools in the examinations by the State Medical Licensing Boards. The publication of lists of those who pass and those who fail has been significant in raising the standards of medical educational institutions. It has also caused the State Licensing Boards to raise their standards of qualification.

Finally, the Council on Medical Education was expanded into the Council on Medical Education and Hospitals. This became necessary because medical education now continues from the medical school into the hospitals in which the young graduates serve their internships and later become residents who will qualify as specialists. The Council on Medical Education and Hospitals lists annually those hospitals which have been found acceptable for the training of interns and residents. Subsequently as a voluntary movement initiated with the Section on Otolaryngology came the establishment of the certifying boards in the various specialties. These certifying boards represent the special societies and the scientific sections of the American Medical Association. The Council on Medical Education and Hospitals establishes a minimum standard for certifying boards. Already more than 30,000 American physicians have obtained the certificates of these certifying boards in the various specialties. One of the present pressing problems of the American Medical Association is the tendency of hospitals to eliminate from their attending staffs men who do not have the certificate of a certifying board.

Drugs and Advertising

Almost immediately following the establishment of the American Medical Association resolutions were introduced condemning the prescribing of patent medicines and nostrums, the adulteration of drugs, and the sale of worthless preparations. Other resolutions condemned physicians who lent the aid of their names and of their prestige to endorsements of such remedies. With the establishment of the *Journal* there came a demand for elimination from its advertising pages of the advertisements of products with secret composition or sold with exaggerated claims. In 1905 the Council on Pharmacy and Chemistry was organized to investigate and report on medicinal products offered to physicians. In 1906 a chemical laboratory was established in the headquarters office as an adjunct to the council. Products which meet the standards of the Council on Pharmacy and Chemistry are permitted to display on their labels a shield-shaped emblem with the words, "Accepted, American Medical Association, Council on Pharmacy and Chemistry".

The home of the American Medical Association, Chicago

The work of the Council on Pharmacy and Chemistry is conducted without any charge to any manufacturer. In fact, the Association pays for all of the work of its councils and bureaus from the dues of its Fellows and the profits on its publications.

The Council on Pharmacy and Chemistry publishes each year a book called *New and Non-official Remedies* which lists all of the newer products not yet admitted to the United States Pharmacopoeia, with methods of identification and statements concerning their actions and uses. The council publishes also an *Epitome of the Pharmacopoeia* with criticisms of products in the *Pharmacopoeia* and also a book called *Useful Drugs*, containing some 250 drugs and preparations which form the basis of teaching in materia medica and pharmacy in most medical schools.

The pattern of the Council on Pharmacy and Chemistry proved so successful that subsequently a Council on Food and Nutrition was established, which deals with food products, and the Council on Physical Medicine which is concerned with apparatus such as the ultra-violet, diathermy, infra-red hydrotherapy, and massage equipment.

Practically all of the State Medical Societies likewise limit their advertising to accepted products. Many of the periodicals published by special medical societies also limit their advertising. This has been one of the most effective activities of the organization.

The next council to be established was known as the Council on Health and Public Instruction. This council was formed with the concept of achieving another objective of the Association—namely, education of the public regarding health and disease and the encouragement of legislation for the improvement of the public health. This council established a speakers' bureau, a special committee to deal with legislation, a division to assemble the law as related to the public health and the practice of medicine in the United States. It developed committees dealing with such special topics as ophthalmia neonatorum, cancer, tuberculosis, and the care of the Indians. Eventually its health educational activities were assigned to a new Bureau

of Health Education in the headquarters office, to a Bureau of Legal Medicine and Medical Legislation, to the publication of *Hygeia*, the health magazine of the American Medical Association which now has a circulation in excess of 200,000 subscribers, and to other agencies *Hygeia* the health magazine, is now published as a part of the editorial functions of the Association

As the interest grew in the field of industrial medicine, a Council on Industrial Health was established

The most recent of the Councils is the Council on Medical Service, which is concerned with the development of voluntary insurance against the costs of hospitalization and of sickness. In association with this council there is a Bureau of Medical Economic Research and the information bureau maintained in Washington, D C, the national capital

Another bureau of the Association is the Bureau of Exhibits, which arranges not only for the scientific exhibit at the annual sessions of the American Medical Association but for similar exhibits at the meetings of the State Medical Societies and at meetings of voluntary philanthropic organizations in the field of health and other exhibits of medical interest. It has taken part in the encouragement of the establishment of health museums, of which there are now about six in the United States

Quackery

Quackery is perennial. The charlatans have preyed on the public in the field of disease and health since the beginning of time. As the *Journal* began to gain prestige it undertook to expose from time to time various charlatans who had achieved great followings in the United States. As a result of these exposes the *Journal* and its editor have been sued for libel—the total number of such suits approaching 40 and the total amount of damages sought being more than \$30,000,000. The *Journal* has gone into court at least six times, since it has never compromised or settled a libel suit. In only one instance did it ever have an unsatisfactory verdict, and in that instance the award to the plaintiff, who was a manufacturer of an alcoholic nostrum for women, was one cent in damages.

Research

Early in its career the American Medical Association offered prizes for essays and other literary contributions to the advancement of medical knowledge. As its funds began to accumulate, the number and the value of these prizes increased. As each of the councils was established, funds were made available for encouraging research, and the Association established also a Committee on Scientific Research, which makes grants to medical investigators. The Association has spent more than \$1,500,000 for such research during the last forty years and has set aside \$2,000,000, the income of which is regularly used for research.

The single room with four employees which represented the headquarters of the American Medical Association in 1899 has grown to a building of half a block in width and almost a block in length, in which more than 700 employees carry on their activities. For these employees the Association has established hospitalization insurance and insurance against the costs of surgery or catastrophic illness.

Early in its career the American Medical Association recognized the importance of the State in the development of preventive medicine and public health. More than any other organization it has the credit for the development of the State Health Departments and of the United States Public Health Service. It has co-operated with every voluntary health agency in assuring adequate return for

the funds contributed by the people in promoting research and in education both of the public and of the medical profession regarding tuberculosis, cancer, blindness, deafness, paralysis, heart disease, and the work of the Red Cross in disaster and catastrophe. Some of its special campaigns have led to the elimination of the hazards of fireworks and gunpowder in celebration of the Fourth of July. It has led in the campaign against motor accidents and the provision of first aid when such accidents occur. It has carefully recorded the progress of the campaigns against death from typhoid and diphtheria. It has stood as the bulwark of medical science against the vast army of the ignorant, the stupid, and the fanatic, the antivivisectionists, the anticreationists, the antimicrobial science groups. All of these functions it has carried on with never an appeal for fund from any agency outside the medical profession itself, never an appeal to any other agency than the medical profession itself to eliminate the evils and misrepresentations. Always it has been the pride of Medicine that it has cleaned its own house, that it has recognized its obligations, that it has met every crisis in its career with its eyes set on greater goals for the good of mankind than have been its objectives in the past.

THE SULPHONE TREATMENT OF LEPROSY

BY

ERNEST MUIR, M.D., F.R.C.S. Ed

Medical Secretary The British Empire Leprosy Relief Association

The drugs commonly known as sulphones are derivative of diaminodiphenyl sulphone

It was their antibiotic effect in controlling the growth of *M. tuberculosis* in experimental animals and *in vitro* (Feldman *et al.*, 1942, Petter and Prenzlau, 1944) that first suggested trial in leprosy. Strangely, they have so far shown much more evidence of usefulness in leprosy than in tuberculosis.

The sulphone derivatives which have so far been tried in leprosy are "promin" (USA, "promin", in England, "promanide") (diaminodiphenyl sulphone-*un* didextrose sulphonate), "diasone" (disodium formaldehyde sulphonylate of diaminodiphenyl sulphone), "promizol" (2,4'-diamino-5-thiasolylphenyl sulphone), and "sulphetron" (tetrasodium phenylpropylamino-diphenyl-sulphone tetra sulphonate). Promin was first used in the National Leprosarium, Carville, U.S.A. (Faget *et al.*, 1943). It was found to be excessively toxic by oral administration but to be tolerated intravenously in daily doses up to 5 g. Following on the first published results on promin, Muir (1944) began a trial of diasone in Trinidad. Fearing that diasone might be toxic by mouth like promin, he first gave it intravenously, but later found that it was well tolerated orally in daily doses up to 2 g. A more recent sulphone derivative, promizole, is considered by the Carville workers (Faget, Pogge, and Johansen, 1946) to give possibly even better results than the first two preparations, though it has not yet been tried out sufficiently. This can be given orally in daily doses up to 6 g. Lastly, sulphetron (B.W. & Co.) is under trial, and the first reports indicate promising results.

The results obtained with these sulphones appear to be similar, though they may vary in the degree of toxicity, the amount of the effective dose, and the speed of results.

Mode of Administration

Suitable Type of Case—It is the lepromatous or severe type of leprosy to which sulphone treatment has been applied—that is to say, the type which so far has been most amenable to treatment by chaulmoogra and other drugs. I have had no experience with sulphones in tuberculoid and uncharacteristic cases, nor have I seen any published results in these types.

Toxic Effects—Faget *et al.* (1943) mention the following toxic signs as occurring: decrease in blood cells, leucopenia, allergic dermatitis, allergic rhinitis, mild and phemeral headaches and nausea, and lepra reaction including iridocyclitis. Further observation has, however, shown that with suitable dosage most of these can be avoided. In my experience anaemia (chiefly due to destruction of red cells) and increased reactionary exacerbations are the two toxic indications to be guarded against, and these are apt to occur principally in patients in poor general health and/or in an advanced stage of the lepromatous type, and in the initial stages of treatment. Before beginning treatment the patient should be examined for anaemia, and when this is present, as it often is in severe lepromatous cases, a preliminary course of full doses of ferrous sulphate or carbonate should be given.

Dosage—My own experience has been chiefly with diasone (Muir, 1944, 1946), and the dosage here described is what is recommended in the use of this drug. Considerably higher doses have been used with promin and promizole (Faget *et al.*, 1943, 1946). It is advisable to begin with small doses in all cases, and gradually raise the amount according to the tolerance of the patient. In doing this the important indications are the stage of the disease, the general condition of the patient, especially as regards febrile and focal reactionary signs, the condition of the blood, and the presence of anaemia. If the haemoglobin percentage is below 70 a preliminary course of iron should be given, and if this is not effective injections of liver extract should be added.

Diasone is generally made up in 5-gr (0.32 g) capsules or tablets. When the haemoglobin is at or over 70%, begin with 1, 2, or 3 tablets according to the general condition of the patient. This should be taken in one undivided dose, preferably an hour after food, so as to promote quick absorption and the highest blood concentration. Reactionary signs are not a contraindication to beginning the treatment, but are a warning not to raise the dose too rapidly. Whatever the initial dose, repeat it every second day for the first week unless they are signs of exacerbation. In strong early cases without septic or other complications one tablet may be added after the first week on the intermediate days and increased gradually till, after three or four weeks, the patient is taking 3 tablets daily for six days a week. It may, however, be a considerable time before a weaker or more advanced case reaches this dosage. The haemoglobin should be tested every week to begin with and iron (and if necessary liver extract) continued in all cases with a percentage below 80 or 90. A fall below 70% or the intercurrent of increased reaction calls for temporary suspension of diasone or diminution of the dose. When a dose of 3 tablets a day for six days a week has been reached it is well to suspend treatment for one week every month. Apparently when full dosage is suddenly resumed after this temporary stoppage the blood concentration rises to a higher level for a time. In patients who have improved

and are free from signs of anaemia and reaction the dose may be gradually raised to 6 tablets daily six days a week for three weeks a month—this being regarded as the maximum average dose, though it may be increased or diminished according to the body weight of the patient.

Effects of Treatment

These vary according to the stage of the disease. In a severe advanced lepromatous case with ulcerating leproma of the limbs, ulceration of the nasal and other mucous membranes with obstruction of breathing, and with severely affected eyes going on to blindness, the first effects, which often take place within a few weeks, are the healing of ulcers, clearing of the nose, and arrest of the eye condition with improved vision.

The next effect is seen in patients with chronic or sub-acute allergic reactions indicated by slight rise of temperature and/or the frequent appearance and subsidence of nodules and other inflammatory skin lesions. These symptoms gradually subside. At the same time permanent nodules and other raised skin elevations become slowly absorbed and flattened out, leaving marked wrinkling of the integument. This improvement generally requires a few months.

The third stage in recovery, and the only one in early or less advanced cases, is the gradual lessening of the number of bacilli found in sections and smears from the skin and in smears from the nose. Thus three plus cases become two-plus and then one-plus, and one-plus cases become negative. The time required for this appears to vary with the advancement of the disease. Some early cases have become negative in four to six months, but more advanced cases may require four, five, or even more years. One of the most striking signs of improvement is that seen in the affected eye and especially in the cornea, where, because of its transparency, the arrest and a certain amount of recession of the lepromatous infiltration can be observed with a lens or corneal microscope.

There is one important point on which evidence is not yet available—that is, whether or not a point is reached at which the type changes, the lepromatous case being transformed into a tuberculoid one with a negative "lepromin" test becoming positive. Theoretically the lepromin test is negative in the lepromatous case because the antigen (the lepra bacilli) are in such great excess of antibodies formed that an effective allergic reaction, which would destroy the bacilli, cannot take place. As the bacillary antigen becomes less and less, is a point reached at which an effective reaction can take place? If so, it would be indicated by a positive lepromin reaction, and we should have an additional factor helping to clear up the residual bacilli. I have found indications in one or two cases that this may occur to some extent, but further evidence is needed.

Length of Treatment

In any case, treatment should be continued at least until repeated bacterioscopic examinations have given negative results over a period of six months to two years, varying directly with the advance of the disease at the beginning of treatment, and with the length of treatment required to produce the first negative bacterioscopic results. Faget (1947) reports that "19 promin-treated patients have been discharged as disease arrested following twelve consecutive months of negative bacterioscopy. Of this number three were under treatment for 1½ to 2 years, three from 2 to 3 years, six from 3 to 4 years, and seven from 4 to 5 years. There have been no relapses. The period of

observation following arrest of the disease has varied from a few months to 2½ years.

Iodides have a specific effect in showing up concealed lepromatous foci. It is possible that their careful administration in cases that have become bacterioscopically negative may be of use in determining the length of further treatment required, and perhaps in speeding up the elimination of residual foci, but this matter still calls for very careful investigation.

Regulation of Established Treatment—Particulars have been given of the dangers attending the initial treatment with diasone. But once the patient has taken his maximum dose for a few months without diminution of haemoglobin content or reactionary symptoms, and has made definite improvement as regards both leprosy and in his general health, the same precautionary methods cease to be necessary and treatment may be continued by an intelligent and reliable patient with a minimum of supervision. A visit by the doctor once a month is often all that is needed. This fact is particularly helpful to patients under domiciliary treatment.

Mode of Action

It is still uncertain how the sulphones act. Fite and Gemar (1946), after examination of biopsy sections from 32 patients under promin, concluded that tissue changes are "atrophic in character with extremely slow and gradual lessening of numbers of organisms in the lesions to the point of final disappearance in 10 of 32 cases examined."

The important finding is that promin appears to eliminate bacillary infection of the blood vessels and blood stream, thereby preventing the formation of new lesions. The atrophy of focal lesions is also more apparent in areas with a more generous blood supply. The results indicate strongly that the best results may be expected in those cases in which treatment is begun in a comparatively early stage of the disease.

A satisfactory hypothesis is as follows. Ordinarily in lepromatous cases the cellular ingestion of bacilli and their multiplication in the cytoplasm result in the formation of "globi," the rounded masses of bacilli found in all typical lepromatous cases. The global bacilli gradually die and are transformed into a non-acid-fast lipid matrix which imbeds the still acid-fast bacilli. Thus in untreated cases the living bacillary element in a globus gradually becomes extinct, and its place is normally taken by fresh globi. It may be supposed that the sulphones act not by destroying bacilli but by preventing the multiplication of bacilli and the formation of fresh globi.

If this hypothesis is correct it would account for (a) The finding of globi in smears from the nose and skin of treated patients, in which there are no acid-fast bacilli or in which the bacilli are thin and ghost-like. (b) The long time required in the clearing up of bacilli in fairly advanced cases. This will be made clear when it is mentioned that human leprosy bacilli, killed by boiling and injected into rats, can still be found retaining their acid-fastness after 18 months.

The Future of Sulphone Treatment

The history of leprosy in the last 30 or 40 years is strewn with the wrecks of so called "cures." Knowing this, one is hesitant to put forward claims for the sulphones which might fail to be confirmed. It will take years before we can say with any confidence what the final results are, whether a complete and lasting cure is possible, what is the relapse rate, and whether relapsed cases will yield to further courses of treatment.

Confidence is given, however, by the fact that experienced workers all over the world who have carried out the initial trials have without exception obtained favourable results such as they had never before found with other remedies. Many have reported definite improvement in practically all cases that have been under treatment for at least six months.

The history of a rising scale of effectiveness in other drugs, such as the sulphonamides, gives reason for hope that sulphone derivatives may be produced which will give even more rapid and effective results.

Sulphones and the Anti-leprosy Campaign

The Supply of the Drugs—Few of the countries where leprosy is rife are wealthy, and the patients who require treatment most are as a rule the poorest of the poor. In a campaign against leprosy there is, therefore, need for a drug which is not only effective but which can be made available to the poorest patient in countries like Africa, India, and China.

Fortunately the raw material of the sulphones is not expensive, and although the outlay on manufacture must at first be considerable the cost should rapidly diminish with mass production. It is calculated that 1,000 5 gr (0.32 g) tablets of diasone should, on an average, suffice for one patient for one year, and the present cost of this is in the region of £6. If treatment is to be extended to a gradually increasing proportion of the one or two million lepromatous cases calculated to exist in the world, there will be a considerable call on the budgets of governments, and on the generosity of philanthropic bodies.

Effect on Control—The two chief difficulties in the control of leprosy have been (a) open infectious cases through ignorance, fear, and shame, or want of opportunity, are not isolated until they have had a chance, often lasting several years, of spreading the disease to their relations and other contacts, (b) that the treatment available has been painful and hard to persist with over a long period and, even when persisted with, has in the majority of lepromatous cases been unable to arrest the disease.

It may be expected that once the effects of sulphone become widely known they will attract early cases which would otherwise have concealed the disease as long as possible. Thus to a gradually increasing extent the danger of infection should be cut off at its source.

Need of Personnel—One of the chief difficulties in anti-leprosy work has always been the lack of doctors. In the medical profession there has been a prejudice against leprosy, either on account of fear or because it was considered that so little could be done for it. In Brazil the Government offers an extra allowance beyond the ordinary service rates. But the best work has always been done by those who have felt they have a vocation, and many such doctors and other workers, once they have overcome their prejudices which surround the subject of leprosy, have become enthralled by the interest of the work. Now that there is a clearer prospect of effective treatment and control, it is to be hoped that more doctors with a pioneering and venturesome (not to say philanthropic) spirit will offer to do this work.

Summary

The sulphones have been found of definite benefit in the severe or lepromatous type of leprosy, clearing up complications, causing a slow but steady diminution of the bacilli, and in some cases bringing about arrest of the disease.

The method of administration of diasone, its possible mode of action, and length of treatment are given in detail.

The effects of sulphone treatment on the campaign against leprosy, the supply of sulphones, and the need of suitable personnel are discussed

TROPICAL EOSINOPHILIA IN EAST AFRICA

BY

H T H WILSON, MB, BChir, MRCP
 (Late M O Colonial Medical Service)

The syndrome now generally known as tropical eosinophilia or eosinophilic bronchitis was first described by Frimodt-Møller and Barton (1940) in Southern India. Under the title "a pseudotuberculosis associated with eosinophilia" they published an account of a syndrome characterized by cough, fever, and loss of weight which ran a prolonged but comparatively benign course. There was a fairly constant similarity in the radiographs of these patients, the characteristic picture showing extensive mottling of both lung fields, resembling somewhat miliary tuberculosis or silicosis. Blood counts revealed a high degree of eosinophilia, and in over half the patients examined 5,000 or more eosinophils per c mm were found.

Weingarten (1943) recorded 81 cases of tropical eosinophilia. He found that expiratory dyspnoea was a prominent symptom and that the spleen was often enlarged. After trying various remedies without success he discovered that dramatic improvement resulted from a short course of neoarsphenamine. Further cases were described in India by Simeons (1943), Treu (1943), Menon (1945), and others, while a similar condition was reported from Ceylon by Carter, Wedd, and d'Abrera (1944), Carter and d'Abrera (1946b), and Soysa and Jayawardena (1945). The Ceylon workers discovered mites of various genera in the sputum of more than half their cases, and considered that tropical eosinophilia might "in part at least be explained on the basis of a mite infestation of the respiratory system". Treatment by inorganic arsenicals was found to be effective with neoarsphenamine and "acetylarsan" by injection, and acetarsol or carbarsone by mouth.

While tropical eosinophilia can no longer be regarded as a rare disease in India and Ceylon, its existence in Africa has not yet been generally recognized. Isolated cases have, however, been recorded by Parsons-Smith (1944) and Stephan (1946) in Cairo, while Ritchie (1944) described the condition in a Tanganyika native serving in the Middle East Forces and Hunter (1946) in a European recently returned from West Africa. The present communication describes an investigation carried out in Dar-es-Salaam, Tanganyika. Differential white counts were performed on a consecutive series of 34 patients attending the native civil hospital with symptoms of recurrent bronchitis or asthma. The patients were all males, and consisted of 29 Indians, four Africans, and one Arab. In 28 cases an eosinophilia of less than 20% was found, while in six cases the eosinophilia ranged from 40 to 78%. The latter group, and a seventh case which was referred on account of an unexplained eosinophilia, were submitted to detailed investigation. All were considered to be suffering from tropical eosinophilia,

six were treated successfully with arsenic, while the condition regressed spontaneously in the seventh case.

Clinical Findings

The characteristic picture appeared to be recurrent attacks of cough, wheezing, and low fever separated by intervals in which the only symptom was a spasm of unproductive coughing in the early hours of the morning. In four cases retrosternal pain was present, and three complained of acute irritation of the larynx and upper respiratory tract. After a variable number of attacks the intervals of freedom became shorter, and cough and dyspnoea caused increasing distress. Early cases showed no constitutional symptoms, but those who had been ill for several months complained of lassitude, anorexia, and loss of weight. Case VII conformed to the clinical type described by Frimodt-Møller and Barton as "pseudotuberculosis". That patient complained of chronic cough, pain in the chest, and occasional small haemoptyses without asthmatic attacks.

X-ray Findings—In three cases no abnormality was seen. In Cases VI and VII there was diffuse mottling of both lung fields, characteristic of the "eosinophil lung pattern," and a suggestion of mottling was seen in the radiographs of Case IV. These cases gave a history of one year's, two years', and ten months' duration respectively.

Pathological Findings—(a) **Haematological**—An initial blood count was done on all cases by Dr Vivarelli. The red cells varied from 4,650,000 to 5,150,000 per c mm and the haemoglobin from 94% to 110% (Lovibond)—comparatively high figures in a country where anaemia is prevalent. Leucocytosis was a constant finding, counts ranging from 11,250 to 34,000 cells per c mm, with an eosinophilia of 52–78%. Except for an occasional eosinophil metamyelocyte no immature cells were seen, the granules varied in size and tended to be larger than normal, they frequently did not fill the cell, and left spaces like vacuoles in films stained by the Leishman method. Whitby and Britton (1942) noted a similar appearance of the cells in eosinophilic leukaemia. Differential counts were repeated two or three times weekly on 200–400 cells, and the percentage of vacuolated cells was seen to diminish in the course of treatment. The blood sedimentation rate was estimated by Westergren's method in three cases, in one case it was raised to 47 mm after 1 hour, but in the other two cases it was within normal limits. Films from all patients were examined for filariae, but none were found.

(b) **Urine and Stool Examinations**—No abnormality was found on naked-eye or microscopical examination of the urine, and specimens of stools were negative for parasites, except in Cases V and VI, in which a few ankylostome ova were discovered by concentration methods. In both cases a rise in the total eosinophils was found when the blood was re-examined after deworming.

(c) **Sputum**—Specimens were repeatedly examined for tubercle bacilli, but none were found. Sputum from Cases II–VI was examined by Dr Vivarelli for mites by the method described by Soysa and Jayawardena. Twenty-four-hour specimens were collected into sterile stoppered bottles, and the mucopurulent material was disintegrated with 10% potassium hydroxide. After it had cleared, enough formalin to give a 10% concentration was added and the liquid left for 24 hours. It was then centrifuged and the deposit systematically examined under the microscope. Four mites of *Tyroglyphus* and a few ova were found in specimens from Case II, one mite of *Tyroglyphus* in Case VI, and an unidentified mite in sputum from Case IV. No mites were found in sputum from Cases III and V.

Treatment

Case II was treated with weekly injections of neoarsphenamine, in the other cases it was intended to follow the method advocated by Soysa and Jayawardena. They gave carbarsone or acetarsol 0.25 g twice daily until clinical cure had been obtained and the eosinophils had fallen to a satisfactory level. Using this method, it was found that a Jarisch-Herxheimer type of reaction occurred between the second and fifth days. This consisted in a brisk exacerbation of symptoms, usually accompanied by some rise in temperature. After two or three days rapid clinical improvement began, with complete and apparently permanent disappearance of symptoms during the next 5 to 10 days. The haematological response was much slower, and the original intention of treatment by a prolonged course of acetarsol was abandoned in favour of a 10- or 12-day course of acetarsol or carbarsone followed, after an interval, by weekly injections of neoarsphenamine. It was found that there was a fairly rapid fall in the eosinophils during the first four or five weeks of treatment, but after this no significant fall occurred until after treatment had been discontinued. Case V was given a 10-day course of carbarsone and four injections of neoarsphenamine, treatment being abandoned when the eosinophil count was still 29%. Two months later the eosinophils had fallen to 4% (a total of 248 per c mm). Case I was of equal severity and Case III was practically asymptomatic. Both were given considerably more arsenic without a more rapid clinical or haematological response being obtained.

In Case II, which was treated with neoarsphenamine alone, the clinical response was slower, but the haematological response was approximately the same as in the other cases.

Case I

An Indian aged 24 had had a cough, retrosternal pain, and a low fever for two to three weeks which were not improved by sulphapyridine and expectorants. On June 2, 1945, the temperature was 99°F (37.2°C), the blood pressure 135/95. Sonorous rhonchi were heard in all areas of the chest and moist rales at both bases. A blood count showed red cells, 5,350,000; haemoglobin, 110%; colour index, 1.02; white cells, 34,000 (polymorphs, 75%; lymphocytes, 24.5%; eosinophils, 66%; eosinophil metamyelocytes, 2%). Most of the eosinophils appeared vacuolated. In three specimens of sputum tubercle bacilli were not found, nothing abnormal was observed in the urine, and no ova or parasites were present in three samples of stools. A skiagram of the chest revealed no abnormality.

On June 4 treatment was begun with acetarsol 0.26 g twice daily by mouth. On the third day there was a sharp rise in temperature which lasted three days and was followed by rapid clinical improvement. By June 17 he was symptom free, and ten days later his chest was entirely clear. On June 28 acetarsol was discontinued after 50 tablets (13 g) had been taken. His white blood cells numbered 11,000 (37% eosinophils). In the course of the next six weeks he was given carbarsone, 0.5 g daily for five days, followed by four weekly injections of neoarsphenamine (one of 0.6 g and three of 0.75 g). On Aug. 18 his white count was 9,600 (19% eosinophils). On Oct. 23 it was 7,176, with no eosinophils. He remained in good health.

Case II

An Indian aged 18 had had recurrent attacks of cough for 12 months. Originally dry the cough had become productive in the last six months, and later he had coughed up large quantities of mucopurulent sputum. Retrosternal pain and increasing dyspnoea had caused him considerable distress, and he had been unable to work for several months. He had had in-patient and out-patient treatment without improvement.

Examination on June 4 showed him to be a thin and dejected individual very distressed by continuous dyspnoea and constant spasms of coughing. The temperature was 99°F (37.2°C). Chest expiration was prolonged and loud sonorous rhonchi were

heard all over both lungs. The spleen was enlarged 34 L (8.9 cm) below the costal margin. The Wassermann reaction and Kahn test were negative. A skiagram of the chest revealed no abnormality. Examination of the urine and stool showed nothing abnormal. Tubercle bacilli were not found in five specimens of sputum. A blood count showed red cells 4,660,000; white cells 13,750 (P, 25%; L, 19%; E, 56%). A sternal puncture gave the following readings: neutrophil polymorphs, 15%; eosinophil polymorphs, 35.2%; basophil polymorphs, 1%; neutrophil metamyelocytes, 5%; eosinophil metamyelocytes, 18%; neutrophil myelocytes, 1.2%; eosinophil myelocytes, 8%; neutrophil premyelocytes, 0.4%; eosinophil premyelocytes, 1%; eosinophil myeloblasts, 1%; normoblasts 7.2%; erythroblasts, 1.2%; macropolycytes and megakaryocytes, 0.6%; mitotic cells, 0.4%. The blood sedimentation rate (Westergren) was 47 mm after one hour, 56 mm after two hours.

The patient was given eight weekly injections of neoarsphenamine (0.15 g, 0.3 g, 0.6 g and five of 0.75 g) beginning on June 7. Four mites of *Tyroglyphus* were found in a 24 hr specimen of sputum collected after the first injection had been given, and a few ova were seen in a specimen collected a week later, but no further adults or larvae. There was an increase in symptoms after the third and four injections, but his clinical condition then steadily improved. By July 28 he was asymptomatic and gaining weight, his total leucocyte count had fallen to 8,000, with 16% eosinophils, and his BSR to 26 mm after one hour.

He was seen again in August, when he complained that he was still getting attacks of asthma. He was repeatedly examined but no abnormality was found in his chest, and his eosinophils had fallen to 10%. Arrangements were made to readmit him to hospital for observation, but he failed to return.

Case III

An African clerk aged 25 was first seen on May 22, with a large number of eosinophils were found in a blood film when he was suffering from an attack of malignant tertian malaria. He was otherwise well except for a slight dry cough. The white cells numbered 8,000 (P, 26%; L, 19%; M, 1%; E, 2%; E, 52%). Nothing abnormal was found in the urine, and no ova or parasites were present in the stools on seven consecutive days. The white cell count on June 6 was 15,500 (P, 10%; L, 18%; M, 0.5%; B, 1%; E, 69%; eosinophil metamyelocytes 1.5%)—15% of the eosinophils showed cytoplasmic vacuolation. The BSR (Westergren) was 9 mm after two hours.

Clinical examination was negative except for a slight splenic enlargement which might have resulted from the malaria. He was given 0.26 g of acetarsol twice daily for 15 days, starting on June 14. After two days his cough increased and a small quantity of sputum was expectorated. This was collected and examined for mites, but none was found. He was entirely free from cough three days later, but his eosinophils still numbered 46% at the end of the course. After two weeks' interval he was given six weekly injections of neoarsphenamine (one of 0.6 g and five of 0.75 g). On July 19 the blood count showed 6,200 white cells, with 12% eosinophils. On Oct. 18 his white cells numbered 6,000 (P, 51%; L, 40%; M, 2%; B, 1%; E, 6%). He has remained in good health.

Case IV

An Indian clerk aged 32 complained of recurrent attacks of dry cough for 12 months. The cough usually woke him in the early morning. In the past four months attacks had grown more frequent and more severe and expiratory dyspnoea had become increasingly troublesome. Treatment had not given him any relief.

On examination on June 11 expiration was prolonged and a few rhonchi were heard at the right base and a patch of inspiratory rales at the left base. The white cells numbered 11,000 (P, 15%; L, 7%; E, 78%). The BSR (Westergren) was 5 mm in one hour. Examination of the urine and stool revealed no abnormality. A skiagram of the chest showed faint mottling of both lung fields. A course of acetarsol 0.26 g twice daily was begun on June 12. Three days later his symptoms became so severe that he abandoned treatment for

days, resuming it on June 19. Sputum was collected at the beginning of the exacerbation and one unidentified mite was found on microscopical examination. The following day he was symptom free, and three days later his chest was clear on clinical and x-ray examination. Treatment was discontinued after a total of 50 tablets (13 g) had been taken, the eosinophils at this time numbering 21%. In view of his high eosinophil count he was given five weekly injections of neoarsphenamine, starting on June 12 (0.6 g followed by 0.75 g). On July 28 his white cells numbered 8,600, with 13% eosinophils and on Oct 23 they had fallen to 6,240 (P, 85%, L, 10%, M, 3%, E, 2%). He remained fit, and stated that he was now feeling thoroughly well for the first time for over 12 months.

Case V

An African cook aged 24 complained of continuous dry cough since an attack of acute bronchitis a month previously. During the last two days his acute symptoms had recurred with cough, wheezing, and fever. On examination the temperature was 99.8° F (37.7° C). Numerous rhonchi were heard all over the chest and a patch of leathery rales at the left base. Neither tubercle bacilli nor mites were found in the sputum. The urine was normal. A few ankylostome ova were found in the stools by concentration methods. A radiograph of the chest revealed no abnormality. The white blood cells numbered 14,600 (P, 20%, L, 15%, M, 1%, B, 1%, E, 63%). He was dewormed with chenopodium and tetrachlorethylene and a blood count on July 9 showed red cells, 4,650,000, haemoglobin, 94%, colour index 1.01, white cells, 20,000 (P, 11%, L, 25%, M, 2%, E, 62%). Treatment was begun on July 9 with carbarsone 0.25 g twice daily for 10 days. On the fifth day the cough and sputum increased and the eosinophils rose to 83%. All sputum was systematically searched for acari but none was found. By July 19 he was symptom free and his chest was clear, but his eosinophils numbered 75%. He was given three injections of neoarsphenamine (0.6 g, 0.75 g, and 0.75 g at weekly intervals). The eosinophils fell to 29% at the end of treatment, and on Oct 24 the white cells numbered 6,240 (P, 65%, L, 25%, M, 6%, E, 4%). He stated that he had had no cough since the beginning of the treatment and that his general health was better than it had been for many months.

Case VI

An African night watchman complained of continuous dry cough with recurrent acute attacks of cough, wheezing, and pain in the chest for the last ten months. He asked to be admitted to hospital, as an acute attack had begun two days previously. When examined on July 10 his nutritional state was poor and there was marked dyspnoea, with rhonchi all over both lungs. The urine was normal. A few ankylostome ova were found in the stools by concentration methods. A blood count showed red cells 4,590,000, white cells 8,750 (P, 30%, L, 30%, E, 40%). He was dewormed with chenopodium and tetrachlorethylene and a blood count on July 28 showed red cells 4,650,000, haemoglobin, 95%, colour index 1.02, white cells, 19,600 (P, 11%, L, 13%, M, 1%, E, 75%). A skiagram of the chest showed mottling of both lung fields typical of the "eosinophil lung pattern". Treatment was begun on July 28 with acetarsol 0.26 g twice daily for 12 days. On the fifth day he became extremely dyspnoeic and his temperature rose to 101° F (38.3° C). Sputum was examined during the acute phase and one mite (*Troglyphus*) was found. By Aug 6 the patient was symptom free and his chest was clear. The course of acetarsol was followed after a short interval by eight weekly injections of 0.6 g of neoarsphenamine. Throughout treatment an eosinophilia persisted, counts varying between 28% and 50%, but on Oct 28 his white cells numbered 8,250 (P, 50%, L, 14%, M, 3%, E, 3%) and skiagrams showed considerable clearing of the mottled pattern. Two months later he was still fit and had had no recurrence of symptoms.

Case VII

An Arab stone-mason aged 30 complained of chronic cough with occasional small haemoptyses. The first attack began 3 months before and had lasted 10 months. It was

followed by 10 months' freedom, then the present attack began 7 months previous to admission.

When examined on July 31 he was afebrile, expiration was slightly prolonged, and there were numerous coarse rales at both bases. Tubercle bacilli were not found in three specimens of sputum, and no parasites were discovered in three stool specimens. A skiagram of the chest revealed diffuse mottling of both lung fields typical of the "eosinophil lung pattern". A blood count showed red cells, 4,950,000, haemoglobin, 98%, colour index, 0.99, white cells, 22,300 (P, 16%, L, 20%, M, 1%, E, 62%, eosinophil metamyelocytes, 1%). He was not seen again until Oct 18, when he was traced and re-examined. It was found that his condition had again regressed spontaneously. A skiagram of his chest revealed no abnormality and white cells numbered 9,360 (P, 70%, L, 20%, M, 6%, E, 4%).

Discussion

The finding of six cases of tropical eosinophilia in a consecutive series of 34 patients suffering from chronic cough or asthma suggests that this condition is relatively common in the Dar-es-Salaam district. All the patients had resided on the Tanganyika coast for the previous two years, and none of them had been out of East Africa for eight years. The only features common to all cases were a history of less than three years' duration, cough of variable degree, leucocytosis, and pronounced eosinophilia. In most cases there was no obvious symptom or physical sign to distinguish them from bronchial asthma or recurrent bronchitis, and it must be emphasized that unless a differential white count is done in the Tropics as a routine on all such cases tropical eosinophilia will constantly be missed.

The aetiology of tropical eosinophilia still remains obscure. It has been found at all ages and in both sexes. Weingarten stresses the importance of environment, finding it common on the coast round Bombay, but absent from the inland district of Rajputana. Although cases have since been recorded from inland districts the majority seem to have contracted the disease in a hot and humid atmosphere. In Dar-es-Salaam the mean temperature varies between 74° and 82° F (23.3° and 27.8° C), with a relative humidity of 60 to 90%.

Löffler (1936) described a syndrome characterized by fever, cough and eosinophilia which resembles tropical eosinophilia but is essentially an illness of short duration in which rapid spontaneous cure occurs. The pulmonary infiltrations described by Löffler were transient ("fluchtige Infiltrate"), seldom lasting more than eight days, and were often confined to one lung. In tropical eosinophilia there is a tendency towards spontaneous cure, but if untreated the condition is apt to persist for several years. It is unlikely, therefore, that the two conditions are identical.

Vaidya (1943) and Lal (1945) do not consider the condition to be a separate disease entity, but think that it should be regarded as a form of asthma with a pronounced eosinophilic response. The relation between tropical eosinophilia and asthma is clarified by regarding asthma or bronchospasm as a symptom common to several diseases, of which this condition is one. Tropical eosinophilia differs from the primary allergic group of disorders in the absence of a family history and in the presence of fever, leucocytosis, splenomegaly, and characteristic shadows in the skiagrams of the chest. Moreover, arsenic is not particularly useful in the treatment of bronchial asthma, and no response was obtained when it was tried in a few of the cases with low eosinophil counts.

As Menon (1945) showed, tropical eosinophilia bears a fairly close resemblance to infectious mononucleosis, and both its clinical appearances and its response to treatment favour the theory that it is a specific infection. Whether

or not the *Acarus* is the infective agent has not yet been satisfactorily proved. The finding of ova and larvae in sputum by Carter and his colleagues and of ova in the present series strongly suggests that the mites are living in the respiratory tract either as commensals or as the direct or indirect cause of the associated symptoms. Carter, Wedd, and d'Abrera (1944) have demonstrated that the mite *Tyroglyphus longior* is killed by exposure to arsenious oxide (1:1,000) for ten minutes. Carter and d'Abrera (1946a) have also produced a syndrome resembling tropical eosinophilia by introducing ova of tyroglyphid mites into the trachea of a toque monkey. Against the theory that the *Acarus* is the infective agent it may be argued that the mites found are not of any specific genus, nor did Carter and his colleagues find that they had entirely disappeared after the patient had been successfully treated. Further research is clearly necessary on this subject, particularly the examination of sputum from patients in the Tropics suffering from pulmonary disorders unassociated with eosinophilia.

Treatment with inorganic arsenic is dramatically successful. Until the aetiology of this condition is understood, and until more cases have been followed up, the minimum effective course of treatment cannot be determined. Vaidya and Lal both record cases which relapsed owing to inadequate treatment, and Soysa and Jayawardena found that the length of treatment should be determined by the blood picture and not by the pulmonary symptoms. In the present series treatment was probably continued in most cases longer than necessary. The most effective method appeared to be a ten-day course of carbarsone followed after a few days by four weekly injections of neoarsphenamine (0.6-0.75 g). This was sufficient to produce complete clinical cure, and further treatment seemed to delay rather than accelerate the fall in the eosinophil percentage. No untoward reactions occurred, nor did any case relapse during the three months in which cases were followed up.

Summary

Seven cases of tropical eosinophilia are described from Dar-es-Salaam, East Africa.

Six of them were successfully treated with arsenic, the seventh regressed spontaneously.

It is thought that this condition must be relatively common on the coast of Tanganyika, and probably elsewhere in tropical Africa.

I wish to express my indebtedness to Dr F. Vivarelli, who undertook most of the pathological investigations described, and to Dr J. H. Macdonald for his assistance in following up the cases. My thanks are due to the Acting Director of Medical Services Tanganyika, for permission to publish this paper.

CAUSALGIA OF THE FACE TWO CASES SUCCESSFULLY TREATED BY SYMPATHECTOMY

BY

JOHN A. W. BINGHAM, MB, MCh, FRCS

Late Major I.M.S. Surgical Specialist No. 7 Indian Base
General Hospital, Surgical Registrar, Royal Victoria
Hospital Belfast

While causalgia most often follows injuries to the median nerve and the medial division of the sciatic nerve, other nerves are sometimes similarly affected. I saw two cases of causalgia of the face, and as such cases are unusual it seems worth while to place them on record. Because of the good results obtained from sympathectomy in many cases of causalgia following injury to other nerves, it thought that this line of treatment might relieve the pain in these cases. As will be seen from the case histories, interruption of the sympathetic chain proved successful.

Case I

An Indian NCO aged 28 was wounded by shell fragment on Feb. 28, 1944. He sustained a small penetrating wound of the right cheek and a severe compound fracture of right leg for which an above-knee amputation was performed. Burning pain on the right side of the face developed on the day he was wounded and was still present when he was seen a day later. It was continuous, was felt in the area of distribution of all three divisions of the trigeminal nerve, and was sometimes confined to this area. It became worse with warmth—when in the sun or on a very hot day—with eating, or with rest. Talking. Marked hyperalgesia of the skin supplied by all three divisions of the trigeminal nerve was present. In the centre of the right cheek was the scar of a small penetrating wound. X-ray examination revealed a small metallic foreign body under the base of the skull in the region of the foramen ovale.

Paravertebral Procaine-alcohol Injection.—A procaine block of the stellate ganglion was produced by the paravertebral injection of 2 ml of procaine on March 17, 1945. Within few seconds, no longer than was required for the procaine to produce a nerve block, the facial pain was completely relieved. A further 3 ml of procaine was injected and was followed by 5 ml of absolute alcohol. The alcohol, unfortunately, produced a neuritis of the upper intercostal nerves, with pain in the back and front of the chest. This was fairly severe at first and lasted for several weeks. Three weeks after the injection the facial pain and tenderness returned and the pain became severe. On examination it was found that the sympathetic block had been only temporary and that sweating returned on the left side of the face. It was decided to interrupt the superior cervical sympathetic ganglion.

Operation.—On April 22, 1945, under local anaesthesia, the right superior sympathetic ganglion was exposed through a 3 in. (7.6 cm) incision along the posterior border of the mastoid muscle. The sympathetic chain was divided below the ganglion, the superior cardiac nerve and communicating rami from the ganglion to neighbouring nerves were cut, and the lower half of the ganglion excised. The facial pain and tenderness were again immediately relieved, and there was no return of their return when the patient was last seen three months later.

This patient also suffered from phantom pain felt in his amputated foot. This, however, was only slightly painful and he did not wish to have anything done for it.

Case II

An Indian NCO aged 23 sustained multiple mortar wounds on April 1, 1944. There were several small penetrating wounds on the left side of the face and head, the left arm and the left shoulder, and an extensive wound of the left thigh. Ten days later the left leg was amputated above the knee for gangrene. Pain in the left cheek began three months after the

injury It was a continuous burning pain, usually confined to the maxillary division of the trigeminal nerve. It was not very severe, but was sufficient to worry the patient considerably. It was worse when he was talking or eating, and he was unable to eat solid food. It also became worse when the weather was warm, and when he was angry or otherwise emotionally upset. On these occasions pain was also felt in the ophthalmic division of the nerve.

When seen almost a year after the injury, pain was still present and was showing no sign of subsiding. The scar of a minute penetrating wound was seen on the left cheek, close to the ala nasi. There was marked hyperalgesia of the skin of the cheek to pinprick and light friction. X-ray examination revealed, in addition to the foreign bodies in the scalp of the left parietal region, a metallic foreign body lying in the left temporal fossa. This had passed from the cheek through the maxilla, and a fracture of the roof of the maxillary antrum was seen in the radiograph.

Paravertebral Procaine alcohol Injection—On March 17, 1945, a procaine sympathetic block produced instant relief of pain, and alcohol injection was performed. Complete relief of pain and tenderness persisted for two months. Simultaneous hyperalgesia and slight pain then returned, and it was seen that interruption of the sympathetic chain had not been permanent. For some months pain did not become severe, and it was at first thought that no further treatment would be required. Later, however, pain increased, and nine months after the alcohol injection it was extremely troublesome. Division of the superior cervical ganglion was then undertaken. **Operation**—As in the first case, on Dec 21, 1945, the lower half of the superior cervical ganglion and a portion of the sympathetic chain were excised under local analgesia. Facial pain and tenderness were relieved immediately.

Discussion

It seems clear from these two cases that, as in causalgia affecting other nerves, sympathectomy will be successful. In some cases of causalgia affecting the trigeminal nerve, as in other cases of causalgia, a procaine sympathetic block should first be performed in order to determine whether relief can be obtained by sympathectomy. Treatment by repeated procaine injections was not attempted in these cases, because even when prolonged relief of causalgic pain is obtained by this means it is sometimes necessary, months or years later, to have further injections, or both these patients this might have presented considerable difficulty.

The aetiology and mechanism of production of causalgic pain and the reason for sympathectomy relieving pain in some cases have been the subject of much speculation. The idea that sympathectomy may interrupt a pain pathway from the periphery has usually been rejected, and a number of other theories have been suggested. For example, Homans (1940), among others, regarded pain and tenderness in such cases as due to peripheral changes brought about by reflex sympathetic impulses, these sympathetic impulses being initiated by afferent impulses passing centrally from the site of injury to a main peripheral nerve or to periarterial pain nerves. Livingston (1944) suggested that persistent causalgic pain is in many cases due essentially to a disturbance of function in the cord or higher centres. Doupe, Cullen, and Chance (1944) suggested that the nature of the nerve lesion in causalgia is a loss of insulation of somatic sensory nerves, and a linkage between them and sympathetic nerves, with the result that they are stimulated by efferent sympathetic impulses.

From observations on and investigations of a number of cases of causalgia and post-amputation pain, however, we have come to the conclusion that when sympathectomy relieves causalgic pain and tenderness it does so by interrupting the sensory pathway.

When the superior cervical ganglion was first exposed in Case II it was noticed that pressure on it caused the patient to complain of pain in the face. About 1 ml of procaine was injected below the ganglion, in the neighbourhood of the sympathetic chain, but not close to the ganglion itself. After this, neither pressure on the ganglion nor pinching the ganglion in forceps caused facial pain. If the facial pain had been produced by efferent sympathetic impulses to the periphery, pain then being conveyed to consciousness by some other pathway, blocking the sympathetic chain below the ganglion would not have prevented facial pain being felt when the ganglion was stimulated. As far as can be seen, blocking the sympathetic chain would have had this effect only if in this way the sensory pathway had been interrupted.

I am indebted to Col S M A Faruki, I M S, Officer Commanding the hospital, for permission to publish these case records.

IN-PATIENT TREATMENT OF THE MALADJUSTED CHILD

BY

ELIZABETH G W BARKER, MB, ChB, DPM.

Assistant Physician St James's Hospital Portsmouth

AND

W LIDDELL MILLIGAN, MD, BSc.

Deputy Physician-Superintendent St James's Hospital, Portsmouth, Assistant Medical Director Portsmouth Mental Health Service

The problem of dealing with the maladjusted child is one which affects the general community, and is now engaging the close attention of large numbers of responsible persons. An attempt to cope with the difficulties is revealed in the establishment of child guidance clinics in most large towns, and the need for this service is reflected in the considerable waiting lists of these clinics. The problem is, however, largely sociological, and the child psychiatrist working in comparative isolation has a very limited scope and can do little to affect the issue materially. As in all aspects of mental health, the need for integration of the medical and social services is paramount, and until this is carried out throughout the country on a large scale the problem will remain unsolved.

The commonest cause of maladjustment is the faulty attitude of either one or both parents, and the treatment and education of parents are, of course, a well-recognized part of child guidance. In many cases, however, this may prove impossible for a variety of reasons, of which lack of co-operation is often the most important. It is essential in such cases that, for a time at least, the child should be removed from the home environment. In other cases it is impossible to give domiciliary treatment because of the child's grossly disturbed behaviour. The provision of foster homes is not always practicable, and even the best of these may not meet the situation. Apart from a few evacuation hostels established during the war, there has been little real effort to cope with the difficulty in this country, and according to Burlingame (1947) a similar position appears to exist in the United States.

During the development of the Portsmouth Mental Health Service it was realized that some provision for child in-patient treatment would have to be made, and ten

years ago the experiment of admitting such children to St James's Hospital was initiated

Outline of the Work

The following is a brief description of the work that has been carried out during the past seven years

Numbers of Admissions—Since 1940 125 children have been admitted. The numbers have increased steadily since the beginning, and in 1943, 1945 and 1946 the admissions were 13, 21, and 48, respectively. The number of boys exceeded the number of girls, and in 1946 33 males and 15 females were admitted.

Ages—The ages varied between 4 and 15 years but the majority admitted were between 7 and 11 years old, with a peak at 9 years for the boys and at 10 years for the girls.

Period in Hospital—The average period in hospital was four months—the longest three years and the shortest six weeks.

placed elsewhere as soon as their general behaviour had settled down sufficiently. A fairly large group were admitted because of suspected epilepsy. Once the diagnosis was established and the condition stabilized the children were allowed to return home and attend as out patients. The more severe cases were placed in a colony. A small number were found to be suffering from organic disease of the nervous system.

Symptoms—A very common combination of symptoms was stealing with enuresis, often associated with running away from home. Aggressive behaviour, with destructiveness and temper tantrums was another common syndrome, and some children showed sexual misdemeanours. Others (mostly older children) exhibited panic attacks and allied hysterical manifestations.

Factors—A very frequent factor was rejection of the child especially by a step parent or by one parent in adoption cases. Alternatively, there may have been a bad home background as in cases where the parents were divorced, separated alcoholics.

Case No and Sex	Age Admitted (Years)	I Q	Referred From	Symptoms	Factors	Length of Illness (years)	Period in Hospital (months)	Disposal	Result	Follow-up	
										Duration (months)	Res.
1 M	11	125	Child guidance clinic	Pilfering truancy running away from home	Parents separated financial stress mother overanxious	1	5	Home	Recovered	6	Very well
2 M	10	106	Court child guidance clinic	Enuresis pilfering running away from home	Not wanted (illegitimate) father alcoholic poor physical health	3	9	Still in hostel Home very unsatisfactory	Improved	—	—
3 M	7	84	School child guidance clinic	Enuresis aggressive behaviour truancy	Defective mother father dead backward	2	3	Home	Very much improved	9	Very well
4 M	6	100	Child guidance clinic elsewhere	Aggressive and destructive behaviour grossly obscene language unmanageable	Parents at loggerheads psychosis—schizophrenic	3	14	Still in hospital	Improved	—	—
5 M	8	92	School child guidance clinic	Enuresis and soiling pilfering	Father away mother neurotic jealous of other children	9/12	4	Home	Very much improved	12	Very well
6 F	13	134	Other local authority	Childish regression panic attacks refusal to eat backward at school	Death of father over anxious mother illegitimacy (?)	1	9	Foster home	Recovered	12	—
7 F	7	112	School child guidance clinic	Solitary moody refusal to make contacts at home (? psychosis)	Sudden death of mother who spoilt her step-mother rejected her	2	7	Home	—	3	Well
8 F	8	78	School child guidance clinic	Destructive behaviour fits, enuresis	Physical defect parents separated mother promiscuous backward	1½	3	National children's home Home	Improved	6	—
9 F	9	80	School out-patient department	Fits uncontrollable truancy	Epilepsy backward	1	3	Home	Much improved	6 No fits for 3 months	—
10 F	7	120	Court child guidance clinic	Pilfering running away from home and school backward at school	Parents separated financial stress mother neurotic	1	12	Home	Recovered	4	Most better

Girls tend to remain longer than boys, the average for the girls being five months and for the boys three months.

Intelligence—Apart from a small group of backward children the average intelligence was well above normal, while some were very intelligent. Many, however, were educationally retarded on admission (for example, in the appended Table, Case 6 had previously been labelled as backward and placed in a special class) but had improved before they left. The average intelligence quotient was in the region of 110, and it is of interest to note that one recently admitted girl of 13 (not included in this series) has a mental age of over 20 years, which gives her an I.Q. of 170.

Sources—Fifty eight per cent of the children were admitted after treatment at the child guidance clinic had proved unsatisfactory either because the child's behaviour was too severely disturbed for it to remain at home or because the home situation was extremely difficult. 6% were admitted via the Magistrates' Court and the child guidance clinic, 20% were admitted from the out-patient clinic at St James's Hospital after the parents and the child had been seen and a report from the psychiatric social worker studied, 4% came from the local education or other authority because the child had proved to be unbilletable in hostels or foster homes, and 12% came from child guidance clinics elsewhere or were referred by the medical practitioners of other areas. Recently the latter group has formed a much higher percentage (30% in 1946).

Problems—All cases were admitted with a provisional diagnosis of maladjustment, though in a small proportion of cases it was suspected that the disturbed behaviour was due to a psychosis and in others that it may have been the result of backwardness. After a period of observation these cases were regraded, the psychotic types treated and the backward children

or promiscuous. Jealousy of another child often appeared, a factor, and evacuation or absence of the father on foreign service was frequently cited by the parents. Very few of the children came from what could be called normal homes.

Correlations—There was a positive correlation between stealing with enuresis and rejection, and also between sex misdemeanours and the immoral life of a parent (especially where the parents were separated).

Placing in Hospital—Owing to the diversity and severity of the symptoms and to the varying sexes and ages, it was not always advisable to treat the children in one ward, and it was useful to have at our disposal the wide facilities which the mental hospital offered. Some children were treated for a time in the male or female admission wards and villas, but the majority were housed in a special wing of the female convalescent villa. Recently a large house in the city has been converted into an annexe to this hospital. The building is situated in quite pleasant surroundings and provides accommodation for twenty children, who are transferred after a preliminary period of observation and if necessary, treatment in the main hospital.

Education—At first daily lessons were given in the hospital by a qualified teacher, but because of the wide age group it did not always prove satisfactory. For over a year now the children have attended the local schools. This has been most successful even where they had previously been very difficult at school, and it helped to promote a feeling of normality in the child. The local education authorities have always proved most helpful over these arrangements.

Treatment—(1) All children were given a thorough physical overhaul and any physical defect or deficiency was, if possible, corrected. (2) As regards general treatment, we have attempted to provide a secure background to the lives of these children.

many of whom have never known consistency or stability always keeping in view our goal, which is that, if at all possible, the child shall eventually return home. We have aimed at a combination of routine with latitude, and of kindness and understanding with the gradual development of a really constructive attitude towards the child. (3) Play therapy has been widely utilized both as individual and as group treatment, and for the older children talks and discussions. (4) We have invited the parents to attend regularly for interviews, and in some cases have had to insist that they keep in touch with us. This is most important, as some parents are only too willing to shelve their responsibilities, and it is very noticeable that in these cases the children lose all their symptoms immediately they enter hospital but relapse very quickly when they return home. (5) Finally, we have tried to return the child to his normal environment gradually by a slowly extending system of group parole days out with relatives or friends, and week end leave.

Disposal—The majority of the children (roughly 80%) returned home, 14% were placed in foster homes or specially chosen institutions (for example, national children's homes) and about 6% went to M.D. colonies or special schools.

Results—Some 80% recovered or were very much improved, and 16% showed some improvement, only 4% showed no improvement. All the children were followed up, either by attendance at the out-patient clinic or by home visits or letters. The Table gives details of 10 unselected cases. All these cases were treated on the general lines described above, with the exception of Case 4, a young schizophrenic who, after extensive psychological treatment both here and elsewhere had failed to produce any result whatsoever, was treated by electric convulsion therapy.

Conclusions

From the foregoing account it will be seen that some 80% of the children were greatly benefited by in-patient treatment. It should be noted that the majority of these had received previous child guidance treatment as out-patients, both here and elsewhere, without any appreciable improvement in their condition. It would seem, therefore, that there is a great need for the provision of in-patient treatment, and it may be of interest to note that since it became known that we were undertaking the care of such children in this hospital we have been inundated with requests to arrange admissions from doctors and local authorities all over the country. It is, unfortunately, only possible to cope with an extremely small proportion of these pleas, which continue to arrive at the rate of about three a day.

We wish to thank Dr Thomas Beaton, medical director of the Portsmouth Mental Health Service, for helpful criticism and permission to publish this article.

Burlingame, C. C. (1947) *Digest Neur Psychiat* 15, Editorial.

The Librarian at the London School of Hygiene and Tropical Medicine, Mr C. C. Barnard, has written an interesting illustrated pamphlet entitled *The History of the Library*. The London School of Tropical Medicine was founded in 1899 by the Seamen's Hospital Society, and by 1904 had collected 373 volumes. The first librarian was appointed in 1915 and in 1921 a library committee was formed and £10,000 invested to produce an annual income for the support of the library. In 1924 the library was incorporated in the newly constituted London School of Hygiene and Tropical Medicine, and in 1929 it was moved into the School building in Keppel Street. Preparations for the recent war were begun as early as 1938, some of the more valuable periodicals being removed to the basement and duplicates evacuated to Kent. On the outbreak of war the library remained open, but in 1941 a large number of books and periodicals were sent to Hampshire and other places. The librarian then made monthly visits to collect books that had been asked for during the preceding weeks and brought them to London or posted them to the required addresses. A valuable adjunct to the library is the instruction in its use—a course of three lectures on tropical medicine, public health, and bacteriology given to students at the beginning of each session preceded by a conducted tour of the library.

Medical Memoranda

Smallpox A Case with Minimal Lesions

About 9.30 p.m. on Monday, Oct 21, 1946, one of the practitioners in this area telephoned me saying 'I have got a case of alastrim with the amber-coloured lesions. I would like you to see it with me to-morrow'. At the consultation next morning I agreed that the diagnosis was smallpox.

The patient, a garage proprietor aged 37, lived with his wife in a flat above his garage in Beaconsfield. He had spent six weeks partly on business and partly on holiday, in Sweden and Denmark. He returned to this country on Oct 3. On Oct 15 he felt sick and complained of a severe headache and backache. When seen by his doctor on Oct 17 he had a temperature of 102° F (38.9° C), the only other sign was a severe stomatitis. He was regarded as a case of influenza and treated accordingly. The feverish illness lasted for three days. On Oct 21 both temperature and pulse became normal, and have remained so ever since.

In consultation the practitioner and myself observed five small suspicious lesions. There were several superficial pustules of an acneiform type widely distributed all over the body, but the suspicious lesions were peripherally distributed—on the right hand, right arm, and the sole of the left foot. Most of them were no bigger than a large pin's head, they were intradermal, and the lesion on the palm of the hand felt 'shotty,' as did the one on the sole of the foot. They all appeared together during the night of Oct 20-21.

The yellow pustular lesion on the palm of the right hand was about 1 cm in diameter, and its base was surrounded by a distinct margin of erythema. It was intradermal and very "shotty" to the touch. The peripheral distribution of the lesions, the short sharp febrile illness, and the site, character, and "feel" of the right palmar lesion in my opinion definitely suggested smallpox.

Dr W. H. Bradley, of the Ministry of Health, made arrangements for one of the smallpox consultants on the regional panel to see the patient with the practitioner concerned and myself the same afternoon. The deputy M.O.H. for the county was also present. At this consultation there was no diagnostic unanimity, but it was decided to vaccinate the patient and his wife. Specimens of blood, crusts, and swabs were sent to Prof. Downie at Liverpool and the patient was isolated. Prof. Downie reported on Oct 25 that the patient's serum gave a negative reaction for variola antibody, and that the material on the swab was insufficient for examination by the complement-fixation test. Further specimens of crusts were then sent to him.

The patient had been vaccinated sixteen years previously. When he was revaccinated on Oct 24 his doctor reported there was an immediate reaction. His wife had been vaccinated in infancy and her reaction to revaccination on the same day was delayed but very marked on the fifth day. Both were kept under general surveillance during the period of isolation. On Nov 1 a wire was received 'Variola virus isolated from crusts and swab'. Arrangements were made through the Bucks County Council and the Oxford authorities to open up the Garsington Smallpox Hospital, where the patient was admitted on Nov 2.

Despite the isolation conditions imposed on Oct 23, several friends, his own garage hands, and some relatives had visited the patient in his flat. There was also the question of laundry and of petrol coupons to be considered. Between Oct 28 and Nov 1 one set of laundry had been collected, put through the laundry and returned, another lot had been sent to the laundry on the morning of Nov 1. To minimize the risk to public health, the workers at the laundry were offered vaccination. 33 were vaccinated on the same day, the remainder during the following weekend—Nov 3-5. As the patient had himself handled the garage petrol coupons during his infective stages these were regarded as fomites. By an arrangement with the Petroleum Department, 2,572½ units in a sealed envelope were burnt, and a certificate to this effect was given for replacements.

All visitors and relatives who had been in contact with the patient, except a squadron-leader and a friend, whose address was unknown, were traced. Of these 9 contacts 2 had been vaccinated during the past two years in the Services, none of the remaining 7 had been vaccinated since infancy and they were revaccinated. The local practitioners, neighbouring local authorities and hospitals were notified.

My thanks are due to Dr Kipping the practitioner, who was convinced throughout that the case was one of smallpox though the lesions were minimal and the clinical picture was that of a patient suffering from a sharp three-day influenza attack which became pyrexial

Suprarenal Cortical Extract for Collapse in Infantile Eczema

Although sudden collapse in cases of infantile eczema admitted to hospital is well known, little has been written concerning treatment. Twiston Davies (1940) suggests that adrenaline can be of value, but states that most patients die in spite of all treatment. The following report of two successive cases seems to indicate the possibility of a more positive approach.

CASE I

A five months old boy was admitted to hospital on Jan 8, 1947, with a history of repeated mild attacks of rash on the face since he was four days old and a severe relapse two days before admission.

On examination he was seen to be a healthy well built baby, with no physical abnormality except a severe weeping and crusting eczema of the head, face, back, and limbs. The temperature was 102.4°F (39.1°C), pulse 120, and respirations 22. Treatment was commenced with starch poultices to all areas. Feeding 6 oz (170 ml) four hourly, half-cream milk, and glucose and water between feeds. On Jan 9 at 9.30 a.m. he was more comfortable and there was less exudation. The temperature was 99.2°F (37.3°C), pulse 90. A calamine liniment was applied to all areas. At noon the temperature rose rapidly to 105°F (40.6°C) and the pulse to 128. Fearing a possible respiratory infection, penicillin in oil, 50,000 units, was given intramuscularly. At 7.45 p.m. the child suddenly became unconscious and cyanosed, the respirations were very rapid and shallow, the pulse uncountable, and the temperature 105.4°F (40.8°C). There were many moist rales in chest and slow coarse nystagmus to the left. Adrenaline, 2 min (0.12 ml) was given subcutaneously, and the respirations at once became slower and deeper, the rales disappeared, and there was a partial return of the response to visual stimuli. At 8.30 p.m. there was a sudden relapse, with rapid respirations and rales, followed by cyanosis and nystagmus. Adrenaline, 1 min (0.06 ml), was given subcutaneously with only partial relief. Five minutes later a further 2 min (0.12 ml) gave greater benefit. At 8.45 p.m. the respirations again became rapid, and prompt relief was obtained with 2 min of adrenaline subcutaneously. At 8.55 p.m. the respiratory rate was rising and adrenaline, 2 min, was given subcutaneously with immediate relief—respirations 35 deep, no rales, pulse 130. The skin was pale and the eczema had nearly cleared. The temperature was found to be 108°F (42.2°C)—and this could not be reduced by tepid sponging. At 9.45 p.m. he had a convulsion, beginning with twitching of the right side of face and neck, and passing to rhythmical contractions of right arm and leg. Reflexes were not obtainable, nystagmus to left. From this time the condition of the child deteriorated, with convulsions becoming more pronounced and spreading to the left side. Later the coma became deeper, with Cheyne Stokes breathing followed by death at 2.20 a.m. the following morning.

The relief obtained in this case, although only temporary attracted attention to the suprarenal gland, and suggested the possible value of employing the cortical extract in addition.

CASE II

A five-months-old baby girl was admitted on April 15, 1947, with a history of rash on both cheeks since she was three months old which spread to the body with increasing severity during the three weeks before admission.

On examination a healthy well-built baby was seen, with no physical abnormality except a severe weeping eczema of the head, face, buttocks, and limbs. The temperature was 98.2°F (36.8°C), the pulse 126, and the respirations 28. Treatment commenced with lead lotion to the limbs, zinc oxide and ichthyol ointment to the body, and ammoniated mercury with tar to the face and scalp. Feeding 5 oz (142 ml) three hourly, half cream milk and glucose and water between feeds. On April 16 the child appeared well, she had occasional cough and there were a few rales in chest. The temperature was 99.8°F (37.7°C), pulse 134, and respirations 34. Zinc oxide and ichthyol ointment was applied to the limbs in place of the lotion. The condition remained the same until the

evening of the following day. At 5 p.m. on April 17 the child was very quiet. The skin condition was clearing rapidly. She vomited after the 4.30 p.m. feed. The temperature was 101°F (38.9°C), the pulse rapid, uncountable, and the respirations 60. The breath sounds were clear. Fluid was not detected in the bronchi. Sodium bicarbonate, 1 teaspoonful to 1/2 pint (284 ml) of water was given 3 oz (85 ml) taken. At 6.45 p.m. the child was comatose but could be roused. Her colour was good. The temperature was 100.5°F (38.05°C), pulse rapid, uncountable, respirations 90. The limbs were flaccid, the eyelids drooping. The breath sounds were clear. The condition of the child was obviously deteriorating rapidly. Adrenaline, 2 min, was given subcutaneously with immediate improvement. There was a partial return of response to visual stimuli, the limbs were flaccid. At 6.55 p.m. her condition deteriorated and the respiratory rate increased. Adrenaline, 3 min (0.18 ml) subcutaneously, and extract of suprarenal cortex ("Eucorione," Allen and Hanburys) 3 min intramuscularly were given with immediate improvement. At 7.5 p.m. she had a relapse. She was very pale, respirations 90, very shallow, the pulse was of good volume, rapid, uncountable. She had divergent squint, the left eye rotated slightly inwards, and the right eye rotated upwards and outwards. The pupils were small and equal. Adrenaline, 5 min (0.3 ml), and cortical extract, 8 min (0.5 ml), were given together intramuscularly, with immediate effect. The respirations were deeper, the breath sounds clear. Active movements of the limbs were very weak. She was trying to scratch. At 7.30 p.m. she was greatly improved. Her colour was good, she was crying and was able to sit up, showing active movements of limbs, and was interested in the surrounding activities. The skin condition was much improved, moist. At 8 p.m. the child was restless, but her general condition gave no indication of the serious state in which it had been one hour previously. The temperature was 99.8°F (37.7°C), pulse 120, and respirations 70. The breath sounds were clear. Glucose and water 3 oz, was taken with avidity, followed by 2 oz of milk and water in equal parts. The child then slept for 2½ hours, and after receiving 2 oz of glucose and water she appeared much brighter. A green frothy stool was passed at 11.30 p.m. From this time the child has given no cause for anxiety.

Cases of sudden collapse in infantile eczema have been known to recover without treatment, but the dramatic results shown in the second case suggest that suprarenal cortical extract should be administered when this serious condition occurs.

I am indebted to Dr P. B. Mumford and Dr M. Peach for permission to report these cases.

Davies J. H. Twiston (1940) *Brit J Derm* 52 182

The annual report from the Medical Department of the Gold Coast Colony contains an interesting account of an outbreak of cerebrospinal meningitis which assumed major epidemic dimensions. Co-operation between all departments made it possible to circumscribe its area, otherwise the whole of the Northern Territories and Ashanti might have been involved. There were 9,863 cases recorded with 1,056 deaths. In 285 of the fatal cases it was not possible to give any treatment. The lowness of the mortality rate is attributable to early treatment with sulphonamide drugs. To ensure immediate treatment small stocks of these drugs were entrusted to the care of the chiefs, with instructions for their use, thus treatment at an early stage, before a medical officer could arrive on the scene, was possible. The epidemic covered an area of nearly 10,000 square miles, calling for extensive travelling by the staff engaged in control. Sulphanilamide was found more effective than sulphapyridine. A chief of any village where a case of sudden suspicious death had occurred, or where spread was expected, was furnished with number of tablets of sulphanilamide and was instructed to give one tablet at once for every double hand span—18 in (46 cm)—of patient's height, and to report immediately to the nearest control camp. If his village was very remote the chief was instructed to repeat the dose in three hours' time. It is stated that faulty diagnosis was unusual, the commonest error being confusion of the condition with pneumonia in children. The mortality rate in treated cases was 7.8%. It is added that the prevention of recrudescence of outbreaks of cerebrospinal meningitis in the north of the Gold Coast depends very largely on the question of housing. The need is to enforce increased ventilation and avoidance of overcrowding. The "fortress" type of house does not lend itself readily to improvement, but the "round house" compound with well-spaced houses, and provided with windows yielding cross ventilation can be made a satisfactory type of community dwelling.

Reviews

MODERN STATISTICS

The Advanced Theory of Statistics Volume II By Maurice G. Kendall M.A. (Pp 521, illustrated 50s) London Charles Griffin and Co

In reviewing the first volume of Mr Maurice G Kendall's *The Advanced Theory of Statistics* (Feb 26, 1944 p 290) we said that a medical journal was not the place in which a detailed examination of a work primarily addressed to mathematical readers should appear. We have, of course, mathematical readers—the intellectual tastes of our profession are catholic—but they will also be readers of statistical and mathematical journals. We did, however, try to indicate the general character of the volume then under notice.

In his second volume Mr Kendall has completed a difficult and important task in a manner which would have been creditable to one able to devote his whole time to the work. To have completed it while engaged in important administrative duties is indeed a triumph. Much of this volume is devoted to a problem which we all meet in professional life, namely that of inferring from the examination of a sample the probable characters of the "population" from which it came. We may, for instance, wish to form a judgment on the general state of nutrition of the inhabitants—say the children of school age—of a large city, but can completely examine only a small number. In the first place, how is the sample to be obtained, how can we be sure that it is a fair sample? The technique of sampling is now well developed, and in the 25th chapter Mr Kendall gives a lucid account of the best methods which does not make very heavy demands on the reader's mathematical knowledge. Next, having an appropriate sample, we pass to the main problem—to form some judgment of the "population" from an examination of the sample. If the sample consists of a hundred children of whom ten are undernourished, the only *certain* inference is that at least ten of the population are undernourished and not so many as 100%. But "common sense" tells us that it is more probable that 10% of the population are undernourished than 1% or 99%. There is no difficulty in answering a question of the following kind. If we infer from the presence of 10% ill-nourished children in the sample that the population does not contain more than $p\%$ defectives, what are the odds in favour of our conclusion being right? It is of course only a probable conclusion, sometimes we shall be wrong, actually the hypothesis was true although our statistical test rejected it. But we may also fall into a different error: not only may we reject the hypothesis when it is true, we may accept it when it is false, when the population *did* contain more than $p\%$ ill-nourished. In the particular illustration there is no great difficulty in handling the dilemma, but sampling even in medical matters, is often concerned with something more complex than a mere dichotomy. The situations which arise are fully examined by Mr Kendall, they present two difficulties of apprehension: the first is to be sure that one fully grasps the nature of the hypotheses under examination, the second to follow the technique of the mathematical solution.

In the last two chapters in the volume, on time series, the author discusses with adequate arithmetical illustration a subject of universal interest. A time series is a set of observations of a variable made usually at equal intervals—say the number of cases of or deaths from measles recorded in successive weeks. It may be that the time series has a steady trend, it may be that it exhibits to the eye what seem to be more or less regular rises and falls, short waves and longer waves. These are of great interest as we all know, to statesmen and economists. They are also of interest to medical men, the alleged periodicity of epidemics of measles is a well-known instance. Our readers will recollect that the late Sir William Hamer first gave statistical reasons for attributing the major waves of the measles graph to the accumulation of susceptible subjects and that in 1929 the late H. E. Soper much extended Sir William's method of analysis. The process was to apply statistical methods to test the adequacy of a plausible biological hypothesis (it may be

said that the wartime effects of evacuation in "aborting" expected epidemics made the hypothesis more than plausible), and the result was to show that it did describe a good deal but certainly not all of the facts. Mr Soper said it gave half the picture. The late Dr John Brownlee followed a different line and applied to the data the method of periodogram analysis used by astronomers, and extracted a number of periods the biological meaning of which gave rise to much discussion. Subsequent mathematical-statistical work, beginning with that of Mr Udney Yule in 1926-7, has made it clear that periodogram analysis is a rather dangerous fool in routine statistical practice. Mr Yule showed that it was quite possible to have time-series which, to the eye, suggested a regular harmonic series, although the waves were not produced at all in the way those who have applied the method of periodogram analysis to economic or epidemiological data supposed.

Mr Kendall who has himself made important contributions to this branch of analysis, has admirably summarized the work of the last twenty-five years, and it is clear that statistical epidemiologists must reconsider the interpretation of so-called epidemic periodicity. It never seemed very probable that arithmetic, however extensive, would enable us to predict accurately when the next pandemic of influenza would afflict the world. Modern research has not increased the probability, yet few will deny that the subject is alluring, and we now have improved tools. Mr Kendall has placed all statisticians, including medical statisticians, under a heavy debt of gratitude.

MAJOR GREENWOOD

ASTHMA

The Treatment of Bronchial Asthma By Vincent J. Derbes, M.D., and Hugo Trisram Engelhardt, M.D., F.A.C.P. With Chapters by a Panel of Contributors. (Pp 466, 61 illustrations, 48s) Philadelphia and London L. B. Lippincott Company 1947

The reception of yet another beautifully produced book on asthma from the United States suggests that the Americans are paying much attention to this disease. The reason, we suppose, from the chapter on climatic and weather effects is probably the climate. No other continent has a cyclonic storminess comparable with that of North America. The wind distributes pollen, spores, and other allergic material widely. The storms of 1934 often heavily coated cars and houses with fine yellow dust that had come from 1,500 to 2,000 miles away.

A group of distinguished authors from different centres in the U.S.A. wrote this unusually interesting book, and editorial control has maintained a balanced presentation of the subject. It is divided into two sections, "Orientation" and "Clinical Aspects". The former is of particular value in providing a historical, statistical, and scientific background to asthma. British readers will particularly appreciate in the clinical section the full account of the non-allergic aspects of diagnosis and treatment. There is a welcome chapter on psychogenic factors in bronchial asthma written by a member of the American Psycho-analytic Association, in which he convincingly discusses the concept of the asthmatic attack as a suppressed outburst of crying. As is characteristic of American books, the part played by allergens, their detection and treatment, is considered in detail, less characteristic is a brief but lucid account of the immunology of asthma. Until recently many have thought that desensitization to pollen or similar antigens was brought about by a combination of the antigen and the cellular antibodies, an analogy being the refractory state occurring after anaphylactic shock. The present hypothesis is that nothing like this happens and there is no reduction of reagin after treating the patient with the specific pollen antigen. What occurs is the production of a new antibody, the "thermostable antibody," which neutralizes the pollen antigen and thus prevents its union with the reagin. However, it is difficult to understand how this theory explains the sensitization to liver which occurs in patients treated by parenteral injections or the rush add that the paper printing, and lay out of this book are most attractive. We have hinted that there are already a great many books on asthma but there is always room at the top and this book looks like getting there.

L. J. WITTS

PAPERS ON SURGERY

The Surgical Clinics of North America Nationwide Number Oct 1946 Symposium on Aseptic Surgical Technique Gastro Intestinal Surgery, Genito Urinary Surgery Issued serially six times a year Sold by 1 year's subscription to six consecutive numbers (Pp 268, illustrated Cloth covers 75s, paper covers 55s) Philadelphia and London W B Saunders Company 1946

This volume contains much information of general interest though some of the articles will appeal chiefly to specialist readers. It begins with an excellent historical summary of the development of aseptic surgical technique, this should be read in conjunction with the later stimulating article in which the author discusses 'unexplained infections' in surgical wounds and claims that the use of ultra-violet radiation in the operating theatre will banish such infections. Sections on penetrating wounds of the chest, plastic surgery of the breast and complications of thoracotomy are useful practical contributions.

The second part covers oesophago gastrostomy, bleeding peptic ulcer, penetrating wound of the abdomen megacolon, and the technique of anastomosis of the colon. The articles are well balanced presentations of the subjects, though in the last mentioned we are surprised to find the Paul-Mikulicz operation relegated to such a secondary position. It is encouraging to note that the mortality from peritonitis consequent on penetrating wounds of the abdomen has been significantly reduced since the advent of chemotherapy by the sulphonamides and penicillin.

The authors of the third part deal with the management of bladder tumours discuss bladder neck obstruction and recommend the use of cotton sutures in vaginal plastic operations. There are two articles of general interest—the first on tests of renal function and the second on the many unnecessary abdominal operations which are performed for overlooked pathological lesions of the genito urinary tract. The concise, clear, and well documented account of the clearance and saturation tests of renal function should be valuable to both physicians and surgeons and the same remark applies to the second article which draws attention to the necessity of considering the genito-urinary tract before undertaking any abdominal operation. The additional article on the removal of foreign bodies in the neck under fluoroscopic control records two such operations which were undertaken in the author's consulting room under local anaesthesia. One of these operations involved a deep dissection in the neck in the neighbourhood of the large vessels and was performed through an incision 3 cm in length. The anaesthetic was not perfect and the patient had to be 'kept in good spirits by a flow of kind remarks'. The bullet was removed, but it is stated that at the end of the operation, which took two and a half hours, the patient was somewhat shocked and his pulse weak. However he soon recovered.

V ZACHARY COPE

Practical Methods for the Microbiological Assay of the Vitamin B Complex and Essential Amino Acids by E C BARTON WRIGHT D Sc, is published in London by Ashe Laboratories at 7s 6d. In this small book details are given of the microbiological assay of riboflavin, nicotinic acid, biotin, pantothenic acid, aneurine, pyridoxine, and the amino acids tryptophane, leucine, isoleucine, cystine, valine, methionine, phenylalanine, lysine, histidine, arginine, and threonine. Chemical methods of assay of these substances are tedious and often of doubtful validity, and biological methods using larger animals are time consuming and expensive. Microbiological methods which have recently come into use have many advantages over biological ones. They are rapid they require no elaborate apparatus and a number of samples can be assayed at one time. The apparatus is such as would be found in any well equipped bacteriological laboratory. Dr Barton Wright gives all the necessary details for performing these assays.

Adventures in many different countries and a youthful sense of humour are the main ingredients of *99 and All That* by the medical man who writes under the pen name FREDERICK KAIGH. A saint's pickled and revered heart showing signs of syphilitic disease, an importunate nymphomaniac, a negro witch doctor employing the latest surgical techniques in the depths of Africa—a character who might have stepped straight out of 'Itma'—are some of the remarkable specimens displayed to us. These leaves from an M.O.'s notebook (published at 9s 6d by Richard Lesley and Co., Ltd.) can be recommended for holiday reading.

BOOKS RECEIVED

(Review is not precluded by notice here of books recently received)

Le Traitement de la Néphrite Aiguë par les Antihistaminiques de Synthèse By François Reubi (Pp 50 3 Swiss francs) Basle Benno Schwabe 1946

A monograph on synthetic antihistaminic drugs, with experimental evidence from rabbits, in the treatment of acute nephritis.

Municipal Health Services By Norman Wilson, M.A. Dipl.P.A. (Pp 178 7s 6d) London George Allen and Unwin 1946

An account of the principles and methods of administration and organization of municipal health services.

Rehabilitation through Better Nutrition Tom D Spies M.D. (Pp 94 20s) Philadelphia and London W B Saunders 1947

A monograph on the long term application of the principles of nutritional therapy, including discussion of vitamin deficiencies and certain anaemias.

Handbook on Mental Health Social Work Published by the London County Council (Pp 114 Post free 2s 8d) London Staples Press 1947

A guide to mental health social workers on the Mental Deficiency Acts and the Lunacy and Mental Treatment Acts.

Gonadotrophines et Tumeurs Testiculaires By M Sorba (Pp 80 6 Swiss francs) Basle Benno Schwabe 1946

An investigation into the production of gonadotrophins and their control in hormone therapy.

Lehrbuch der Nervenkrankheiten By Dr Robert Bing 8th ed (Pp 743 52 Swiss francs) Basle Benno Schwabe 1947

Textbook of neurology revised in the light of recent neurological research.

Homoeopathy and Chemotherapy By O Leeser, M.D. (Berlin) (Pp 87 7s 6d) London Hippocrates Publishing Company 1947

Discussion of chemotherapy from the homoeopathic view point.

The Contribution of Homoeopathy to the Development of Medicine By O Leeser, M.D. (Berlin) (Pp 69 7s 6d) London Hippocrates Publishing Company 1947

An account of various aspects of homoeopathic teaching.

A Textbook of Dietetics By L S P Davidson, M.D. FRCP FRSE and Ian A Anderson B.Sc., M.B., Ch.B. 2nd ed (Pp 517 21s) London Hamish Hamilton Medical Books 1947

Discusses the practical problems of dietetics for students and general practitioners, includes recent work.

The British Encyclopaedia of Medical Practice Medical Progress 1947 (with cumulative supplement) Edited by Lord Horder (Pp 525 42s for 2 vols) London Butterworth 1947

Includes critical surveys of medicine by Lord Horder, surgery by Sir Max Page, and obstetrics and gynaecology by Prof F J Browne.

The Glands of Destiny By Ivo Geikie Cobb, M.D. 3rd ed (Pp 258 15s) London William Heinemann 1947

A simple account of endocrine glands and of their effects in well known historical personalities.

The Art of Healing By Bernard Aschner, M.D. (Pp 336 12s 6d) London Research Books, Ltd 1947

The author discusses the place of many ancient remedies in present day medicine.

The Medical Register, 1947 Published for the General Medical Council (Pp 2274 22s post free) London Constable 1947

Recent Trends in Alcoholism and in Alcohol Consumption By E M Jellinek, Sc.D. (Pp 42 \$0 50) New Haven Connecticut Hillhouse Press 1947

An analysis of alcohol consumption statistics and the prevalence of alcoholism in America.

The Mystery at Orchard House By Joan Coggin (Pp 158 9s) London Hurst and Blackett 1947

A detective story.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JUNE 7 1947

CENTENARY OF THE AMERICAN MEDICAL ASSOCIATION

The American Medical Association is next week meeting in Atlantic City, New Jersey, to celebrate its one hundredth anniversary and the programme of the activities that will take place from June 9 to June 13 suggests that this memorable occasion will be altogether worthy of the event and of American medicine. The American Medical Association has invited a number of medical men from this country to take part in the meeting. Those who will speak as distinguished guests at the various section meetings include Sir Howard Florey, Sir Heneage Ogilvie, Sir Stewart Duke-Elder, Prof John McMichael, Prof G W Pickering, Prof H J Seddon, Dr A R Hunter, Dr R M B MacKenna, Mr G E Martin, and Dr E A Underwood. The British Medical Association will be represented by the Chairman of Council, Dr H Guy Dain, the Chairman of the Organization Committee, Dr J A Pridham, and by the Secretary of the BMA and the Editor of the *Journal*. The British visitors are honoured by the invitation and are assured of a warm welcome from their professional colleagues in the USA. We have pleasure in printing in the opening pages of this issue an article on the history of the American Medical Association from the pen of Dr Morris Fishbein, Editor of the *Journal of the American Medical Association*.

What first strikes the British observer of the American scene is that the BMA and the AMA are almost contemporaries, because it was only fifteen years ago that the BMA completed the first 100 years of its history. The birthplace of the BMA was the provincial cathedral town of Worcester, the AMA may be said to have been conceived in New York and born in Philadelphia. A meeting was held in the Medical Department of New York University in May, 1846, at which 80 medical delegates from some of the States were present. Dr Nathan Smith Davis was the Chairman of a committee appointed to bring the subject of medical education before the Convention. This committee put forward four principal proposals. It was desirable, the committee felt that (1) a National Medical Association should be founded in the USA, (2) a uniform and high standard for the MD should be adopted by all medical schools, (3) before a young man started as a medical student he should have a suitable preliminary general education (4) a code of ethics should be adopted for the medical profession. The New York Convention of 1846 also set up committees to consider the registration of births, deaths, and marriages, and the establishment of a nomenclature of diseases to be adapted to the USA. Exactly a year later on May 5 1847, the delegates to

the National Medical Convention met in the hall of the Academy of Natural Sciences in Philadelphia. Reports were made on the matters discussed the previous year, and it is worthy of note that the resolution on medical education recommended that a young man, before being accepted as a medical student, should be of good moral character and should have acquired "a good English education," a knowledge of natural philosophy and of elementary mathematics, and such acquaintance with the Latin and Greek languages as would enable him to appreciate the technical language of medicine and to read and write prescriptions. Dr Nathan Smith Davis, who may justly be described as the founder of the American Medical Association, also made the interesting recommendation that a committee should be set up to record the indigenous medical botany of the USA.

The Convention finally got down to the difficult question of organization, and after much discussion on the proposed National Medical Association it was proposed that "This institution shall be known and distinguished by the name and title of 'The American Medical Association'." As a preamble to the constitution the purpose of this Association was declared to be

- for cultivating and advancing medical knowledge
- for elevating the standard of medical education,
- for promoting the usefulness, honour, and interests of the medical profession,
- for enlightening and directing public opinion in regard to the duties, responsibilities, and requirements of medical men
- 'for exciting and encouraging emulation and concert of action in the profession,
- for facilitating and fostering friendly intercourse between those engaged in it'

The founding fathers of the AMA, meeting in the city where the constitution of the United States had been drawn up 60 years before, urged the formation of State and local societies. Nathan Smith Davis, who for so many years was to be a powerful guiding force in the AMA, was always proud that it was based democratically on local medical organizations and institutions. The foundation stones of the AMA were medical education and medical ethics. The ethical principles adopted were with little alteration those propounded by the English physician Dr Thomas Percival, FRS, who published his code of ethics in 1803. When the code was presented to the National Medical Convention in May, 1846, Dr John Bell observed "As it is the duty of a physician to advise, so has he the right to be attentively and respectfully listened to—an observation which has a strangely modern ring to it. The AMA, particularly through the *Journal of the American Medical Association* has always been a forthright opponent of quackery and has always attacked the purveyors of nostrums and secret remedies with a freedom and courage which we may envy. The attack on these evils began in the very first week of its foundation.

One hundred years ago medical education in the USA was, to say the least, in an unsettled and unsatisfactory state. Between 1830 and 1845 medical colleges doubled in number and the majority of them were conducted on a commercial basis. By shortening the curriculum and making the terms of graduation easy in order to attract

students and their fees the managers of these colleges did a great disservice both to medicine and to the community. Three years before the A M A was founded Nathan Smith Davis attacked the abuse of the procedure whereby medical students were taught and licensed by the same college. In 1869 we find Dr William O Baldwin, who was the president of the New Orleans annual meeting, stating that "almost any body of medical men may obtain a charter for a medical college in most of the States of this Union, with pretty much the same regulations and privileges as they may agree upon among themselves and ask for." The A M A continued its uphill struggle for the reform of medical education and an important step was taken in 1905 by the formation of a Council on Medical Education, to which a full-time secretary was appointed, there had before this been a Committee on Medical Education. This Council, as Dr Fishbein points out in his article, "undertook to examine the medical colleges and to establish a minimum standard of medical education." It graded medical colleges into Class A, Class B, and Class C. The results of this wholesome classification were published. In 1905 less than 20% of the 165 medical colleges in the USA came under Class A. To-day the 77 medical colleges in the USA are rated as Class A, and there is one medical school in inglorious isolation in Class C. As Dr Fishbein puts it "The stimulus to improvement was simply annual publication of the facts to both the medical profession and the public." The Council on Medical Education was finally enlarged into the Council on Medical Education and Hospitals. In 1905, also, the Council on Pharmacy and Chemistry was established, although there was much opposition to it—it was described as "the most important and effective measure ever undertaken by this Association to rid the profession of the abuse of the nostrum evil." A year later the Council on Pharmacy and Chemistry asked the Board of Trustees to provide them with a laboratory. The fierceness of the attacks from many quarters on the activities of the Council showed the extent of the evil it set out to combat and the fears of those who anticipated the financial loss of exposure. Needless to say, the Council on Pharmacy and Chemistry successfully rode the waves of opposition and its service to medicine is deeply appreciated by those who are familiar with its reports published in the *Journal of the American Medical Association*.

In the early years of its existence the A M A published an annual volume of *Transactions*, and the value of these *Transactions* was repeatedly questioned by members. A Committee on Medical Literature drew attention to the fact that many medical editors had abandoned their work for other professional activity and that "some had tired of their ill-paid toils and thankless duties, some had been snatched away by the hand of death"—to quote from Dr Fishbein's "History of the A M A."

Dr S D Gross had been to England to look into the way the British Medical Association conducted its affairs and as a result he suggested that the *Transactions* be discontinued and replaced by a periodical publication. The matter came to a head at the meeting of the A M A in New York City in 1880. In his Presidential Address then, Dr Lewis A Sayre urged that the example of the British Medical

Association be followed. "It is very questionable," he said, whether the mode pursued by the British Medical Association, in establishing their own journal, would not be an immense improvement on our present method. The British journal is the exclusive property of the Association, and by the liberal compensation of an accomplished editor, a weekly edition is issued, instead of an annual volume. Dr Sayre attributed the success of the British Medical Association to its journal and observed also that its advertising columns made a useful contribution to its funds. He considered that the combination of an association and a journal in the hands of an editor given full discretion on what to publish was congenial to American ideas. "It is," Dr Sayre observed, "dependent for its success on the intelligence, union, and good will of the members." Above all, it is a most successful and influential means of increasing the membership, enlarging the power, and widening the basis of the association and of making it a living organism during the intervals between the annual meetings. Dr Nathan Smith Davis was a member of the committee set up to consider Dr Sayre's recommendations, and a resolution was passed that a weekly journal should be established. The first number of the *Journal of the American Medical Association* appeared on July 14, 1883, and a year later it was announced that as a result of the publication of the *Journal* the income of the Association had increased. It is pleasant to record the fact that in founding the J A M A the American Medical Association freely consulted the then Editor of the *British Medical Journal*. Mr Ernest Hart, who was invited to go to America to advise them on how such a journal should be launched. A Board of Trustees was set up in 1882 to be responsible for the financial conduct of the *Journal* and to appoint the Editor. The Board then consisted of nine members who served for a term of three years.

The guiding hand of Nathan Smith Davis is clearly visible in the evolution of the American Medical Association up to the end of the 19th century. Throughout the first quarter of the present century the successful expansion of the A M A's activities owed much to Dr George H Simmons—an Englishman by birth and an American citizen by adoption. Dr Simmons became Editor of the *Journal of the American Medical Association* in 1889 and subsequently joined this office with that of Secretary and General Manager. His influence made itself felt in the reorganization of the A M A in 1900, in his establishment of the printing works of the A M A, in the development of the nine specialist publications issued by the A M A and in the publication of a Medical Directory and of that indispensable instrument of medicine the *Quarterly Cumulative Index*, the successor to the *Index Medicus*, founded by John Shaw Billings and continued by Robert Fletcher and Fielding H Garrison. When Dr Simmons resigned from the Editorship in 1924 he was succeeded by Dr Morris Fishbein, from whose "History of the A M A," which has been appearing in the *Journal of the American Medical Association* since November last year, the facts recorded in this article are taken. Dr Simmons often expressed his wish to be relieved of the duties of Secretary, and an important step was taken in 1922 when Dr Olin West was appointed Secretary of the American Medical Association.

Dr West retired from this position in 1946. He was succeeded as Secretary by Dr George F Lull, and his services to the Association were recognized by his selection as President of the Centenary Meeting at Atlantic City. Most unfortunately ill-health has prevented him from filling this distinguished office and the Centenary Meeting will be presided over by Dr Edward L Bortz, of Philadelphia.

There are now about 190,000 medical men in the U.S.A., and of these 130,000 are members of the American Medical Association. American medicine owes much to the A.M.A., and it is indeed remarkable how great an influence on American life has been exerted by a voluntary organization of professional men, well organized, and wisely led. This great American Association will continue to lead the American medical profession in its adaptation to the changing conditions of modern life, and in doing this it will without question take a firm stand on the principles on which it was founded.

LEPROSY AND ITS PROBLEMS

Leprosy is still a most mysterious disease. An acid-fast bacillus is undoubtedly the causal agent, but failure to transmit and to propagate this bacillus in animals has resulted in failure to determine the means by which infection is transmitted to man. There have been, and there still are, many curious theories to account for human infection. Some African peoples consider that the breaking of food taboos is the real cause. The Lobi, one of the rather primitive tribes which dwell on the banks of the Volta, are convinced that if gold dust comes in contact with their skin they must inevitably acquire the disease. In mediaeval Europe infection was thought to be transmitted either as a venereal disease or by the breath, so that lepers in many areas had to cover the nose and mouth with a cloth. Then came the era when decaying fish was believed to be the "true cause, while to day, though it is generally agreed that leprosy is a disease of low infectivity for man, there is still uncertainty as to how far malnutrition and close association with lepers in conditions of squalor are the main predisposing causes. A new theory has recently been put forward by Moissier,¹ who believes that cockroaches carry lepra bacilli, infection from man to man would then be indirect.

If more were known of the means of transmission we might have a clue to the reasons why at the end of the Middle Ages leprosy practically died out in Western Europe. In the early years of Christendom the disease, which hitherto had been confined to the East, crept slowly along the Mediterranean littoral and by the ninth century it had become firmly established in Western Europe. Yet even hundred years later leprosy was to be found only in a few out-of-the-way corners. The last British leper whose infection could not be traced directly or indirectly to the Tropics died in 1798 in the Shetland Islands. Was the disappearance of leprosy due to improvements in hygiene and nutrition? It hardly seems likely, for even in mediaeval Europe though leprosy was largely a disease of the poor, there were rich and important lepers. Robert the Bruce

was possibly not a leper, according to MacArthur,² though Louis XI of France may have been, and Baldwin IV, King of Jerusalem, undoubtedly was. Poverty and malnutrition did not cease in England with the coming of the Tudors, in fact, the "sturdy beggars" of Queen Elizabeth's reign were a national problem. If the development of the infection were dependent solely on poor food and worse hygiene it might have been expected that leprosy would have been rare among those Africans who during the war enlisted in the armed Forces, where their food and general living conditions were far better than anything they had previously experienced, yet leprosy developing during their army career was by no means rare even among men with four to six years' service. Nevertheless the appearance of leprosy in a few Europeans who were interned in the Far East, as recorded in the *Journal* of May 24 (p. 731), suggests that malnutrition must play a considerable part in increasing susceptibility to infection.

Was the disappearance of leprosy in Europe due to the isolation enforced? As early as A.D. 583 the Council of Lyons, following the stringent rules laid down in the Old Testament, had prohibited the free movement of lepers. In England the first leper house, of which there were to be more than a hundred, was founded at York in A.D. 936, though in Scotland the isolation of lepers did not begin till 1226, when a leper hospital was built at Rothfarnham. Lepers were treated as dead and were forced to announce their approach by means of clappers. There must therefore have been many who evaded inspection for leprosy, for people are ever reluctant to face a living death, and, as in Africa to-day, many must have escaped detection until they became too disfigured or too weak to work. Mediaeval leprosy certainly disappeared without any great change in medical treatment, apart from isolation. Although Gilbert, Bernard de Gordon, and others urged an adequate diet the main idea in treatment seems to have been to feed the leper on the worst possible food. Coulton³ mentions an agreement entered into in 1356 by which the city fathers of Oxford graciously granted to the Chancellor of the University jurisdiction over the market "and over all flesh or fish that shall be found to be putrid, unclean, vicious, or otherwise unfit on this condition, that the things forfeited be given to the Hospital of St John." This idea evidently became popular, for Comrie⁴ records that the Scottish Parliament in 1386 agreed that the flesh of wild beasts found dead must be given to lepers, as well as all pork or salmon found corrupt in the market. The town of Berwick-upon-Tweed thoughtfully added a rider that "if there be no leper-folk, the rotten pork or salmon shall be utterly destroyed."

If individual treatment was ever attempted there were various sovereign remedies. Three black serpents should be caught, their heads and tails cut off, and then middle portions burned in a new pot, white soap and oil were to be added and the whole rubbed in a mortar until thick like honey. This material was applied for three days and the part well washed. If any of the infirmity were left all that was needed was to behead a tortoise, collect its blood,

and anoint the affected parts with a feather.⁵ The Portuguese in the fifteenth century believed in shipping their lepers to one of the Cape Verde Islands, where the unfortunates lived like aldermen on a diet of everlasting turtle soup. In the meantime both in India and in China chaulmoogra oil had been used in the treatment of leprosy for many centuries. It was first introduced into western medicine in 1854 by Mouat,⁶ who reported improvement in a case of leprosy after its oral administration and local application. Although chaulmoogra has since then been used in all forms of leprosy there is still doubt as to its efficacy. McCoy,⁷ for instance, in view of the meagreness of the data available and the tendency of many cases to improve spontaneously, is left after twenty-five years' personal experience 'with the very definite impression that chaulmoogra oil and its derivatives are of doubtful value in the treatment of leprosy'.

Dr E. Muir draws attention on page 798 of this issue to a new and more hopeful outlook in the treatment of leprosy by means of the sulphones. Cowdry and Ruangsiri⁸ were the first workers to find that promin had some curative action in rat leprosy. Later Feldman and his colleagues⁹ demonstrated the beneficial action of promin in tuberculosis in guinea-pigs, while Faget and others,¹⁰ who had previously failed to note any improvement in human leprosy from sulphanilamide, sulphathiazole, sulphapyridine, and sulphadiazine,¹¹ promptly used it on human lepers, reporting far greater benefit than with any other sulphonamide derivative. As Dr Muir emphasizes, the action of sulphones has not yet been fully tested in all forms of leprosy. Nodular leprosy may possibly prove intractable, for according to O'Leary and his colleagues¹² sulphones such as promin are less active than streptomycin in curing skin tuberculosis. Nevertheless the 2,000,000 lepers in the world, of whom 97.5% are Indian or African, may well take heart, as may those few Europeans who have been so unfortunate as to contract leprosy during the war. An important step has been taken and one which may perhaps end in freeing the world from the scourge and dread of leprosy.

STREPTOMYCIN AND T B MENINGITIS

Medical men and the lay public are worried about the question of streptomycin in the treatment of tuberculosis. Occasional appeals broadcast by the B.B.C. on behalf of individual cases increase the anxiety that is felt, and perhaps do more harm than good, because the response to these appeals seldom produces enough "open market" streptomycin to treat the patient in need of it. To discuss the problems that arise from this situation the British Medical Association last week held a conference which was attended among others by representatives of the Ministry of Health, the Ministry of Supply, the pharmaceutical industry, and by Sir Alexander Fleming. The conference concluded at the end of its session that it could make no useful statement to the public. Nevertheless those who attended left with a clearer idea of what the difficulties were as seen by the

research worker, the Government departments concerned and not least the medical practitioner and his patient.

Streptomycin is available in this country in only very small quantities, and these small quantities are being allocated to centres where research can be carefully conducted. There is still much to be discovered about streptomycin, and both medical men and the public must await the information that will be contained in a report from the Medical Research Council later this year. What worries doctors and patients particularly is the difficulty of obtaining the drug for cases of tuberculous meningitis. There is not enough streptomycin to treat all the cases of tuberculous meningitis that exist—a fact which needs emphasizing. Hospitals providing beds for the treatment of tuberculous meningitis with streptomycin are the Great Ormond Street Hospital, the Postgraduate Hospital at Hammersmith, Guy's, the National Hospital for Nervous Diseases in Queen's Square, the Alder Hey Hospital in Liverpool, and the Glasgow Hospital for Sick Children. The fact that only six hospitals in England and Wales and Scotland are making available only some of their beds for the treatment of tuberculous meningitis is in itself an index of the extremely small quantities of streptomycin available. We understand too, that at present only children up to the age of 7 can be accepted for treatment.

It is hoped to increase the supply of streptomycin, and much will depend on the nature of the report expected from the Medical Research Council. Whether more streptomycin might have been obtained, and whether some better organization for treatment could not have been devised, are legitimate questions to ask. For example it is worthy of note that France is able to obtain more streptomycin than England. Is this because of the doctor's situation, or is it because French administration moves more quickly? Prof. Debré has been able to set aside fifty beds in his hospital in Paris for the treatment of tuberculous meningitis with streptomycin, and apparently he has enough of the drug for the purpose of his investigation. We doubt whether anything on a similar scale is being attempted in any one hospital in Great Britain. It is true that the treatment of tuberculous meningitis is in the experimental stage and doubts have been expressed about its ultimate benefit, but these doubts will not be removed and the problem will not be solved until the research worker is given enough beds and an adequate supply of the drug. The report of the French investigation is eagerly awaited.

PENICILLIN TREATMENT OF GONORRHOEA

A. Fischer¹ reports some interesting facts about the treatment of gonorrhoea in Switzerland. Towards the end of the sulphonamide period only 30% of the cases were fully susceptible, 40% being absolutely, and 30% relatively, resistant. The advent of penicillin changed the outlook as radically as had the introduction of sulphonamides in 1936, since it provided the solution to the problem of the sulphonamide-resistant case. Fischer reviews the results obtained with penicillin in 3,600 cases reported by others and describes those achieved in the treatment of 180 cases in Zurich in 1945. All had a series of intramuscular injections at intervals of two or three hours during the course of a single day. A total dose of 100,000 units gave results slightly inferior to those following 150,000 units. Relapse cases received a further course, sometimes 200,000 units, most of them responded to the second course and all those requiring it to the third. Tests of cure included chemical provocation by silver nitrate instillation and "biological" provocation by a dose of gonococcus vaccine. It is the

necessity for such tests and for the expert examination of the secretions obtained which maintains the treatment of gonorrhoea in the specialist category. The administration of the drug is simplicity itself, and if an oil preparation is used of which a single dose will really maintain an effect for sufficiently long it becomes simpler still. All complications were found to respond equally well to this treatment except arthritis, which is known to require a much larger dosage. The dose which it is advisable to use in primary gonorrhoea is limited by the danger of obscuring the manifestations of coincident syphilis. Even so, every patient treated for gonorrhoea with penicillin should afterwards be kept under observation for syphilis. In some of Fischer's cases the development of a positive Wassermann reaction was delayed even by the small dose of penicillin used. A commendably large number of partners is included in this series. Evidently the organization in Zurich makes every effort to treat the source of the infection as well as the patient. In women known to have conveyed the disease gonococci were often not found, though whether cultures as well as films were made is not clear, they were nevertheless treated.

THE ROYAL SOCIETY

Sir Robert Robinson, president of the Royal Society, received the guests at a conversazione at Burlington House on May 29. The many scientific exhibits and demonstrations had been arranged for the occasion by individual scientists, industrial firms, and national research institutions or museums. They ranged from an ingenious model illustrating the release of atomic energy by the uranium chain reaction, to the mandible of a giant hyracoid from the Lower Miocene beds of Rusinga Island, Lake Victoria. The uranium model was set up by the Science Museum, and the successive release of table-tennis balls, representing neutrons, made it all appear like a charming game for advanced children. Alongside the giant hyracoid jaw were the skull and antlers of a Pleistocene fallow deer, while in keeping with the atomic toy were demonstrations of plastic optical components made by reproduction from a master mould by what ICI call the "surface-finishing" process, and an apparatus from the Cavendish Laboratory, Cambridge, showing the use of radar techniques for the measurement of the velocity and absorption of ultrasonic waves in liquids.

An item of medical interest from the Clarendon Laboratory at Oxford was a "radiation-fluxmeter" developed after investigation of a number of serious accidents with radiant heat apparatus. This instrument consisted of two thermocouples attached to two blackened disks, one of which was exposed to the source of radiation. The air temperature at both disks was the same and the difference in radiation energy impinging on them could be measured for all frequencies from the visible to the far infra red. A collection of late seventeenth and early eighteenth century microscopes was exhibited by the Wellcome Historical Medical Museum. The Lister Institute showed a crystalline bacterial enzyme. This was the enzyme catalase which decomposes hydrogen peroxide to oxygen and water. It has been isolated from *Micrococcus lysodeikticus* and was said to be the first bacterial enzyme to have been obtained in a pure state. The enzyme is an iron-porphyrin-protein and lysozyme was used in one of the preliminary processes leading to its isolation. The exhibit prepared by the Molleno Institute, Cambridge, included electron photographs of virus crystals. A new plant virus recently crystallized is notable as the only virus known to be transmitted by a flea beetle and the only insect-transmitted virus in this country not carried by a sap-sucking insect. Thus

once again the Royal Society took the opportunity of presenting to its many distinguished guests a series of vivid demonstrations of work that is going on in almost every branch of science.

HOMELESS CHILDREN IN SCOTLAND

In the spring of 1945 the Secretary of State for Scotland appointed a strong committee of lawyers, magistrates, and eminent lay persons, including two women doctors, to sit under Mr J. L. Clyde, K.C., to investigate the existing provision for children who have no normal home life and to suggest the best measures to compensate for their lack of parental care. The committee's report¹ recommends as a first measure that the care of these children, which is divided between three Government Departments, should be transferred to one department. At present homeless children in every local authority area come under the Education Committee, the Public Health Committee, and the Public Assistance Committee. The report proposes that one committee only should look after these children, with powers and duties extended to give it a uniform jurisdiction. The best solution of the problem, in the opinion of the committee, is a good foster-parent system; this is best suited to provide the child with the necessary individual attention and scope for development of independence and initiative. The way to improve the system is to choose and inspect foster-parents with greater care and discrimination, and to employ more highly trained officers. A standard minimum rate of payment to foster-parents should be fixed for all authorities, and financial gain must never be the main motive. Responsibility for the boarded-out child should rest on the boarding-out authority, as at present. This means, admittedly, an undesirable variation of standards where a number of different authorities are boarding children out in the same small area; on the other hand, if the authority of the area of residence were made responsible, it would be tempted to pass on the difficult children to other areas, disregarding their welfare. The authority of the area should, however, have a right to receive previous official intimation and to exclude a child, subject to appeal. Unsatisfactory foster-parents should be immediately notified to the department. Before being boarded out all children should go to a home for medical and other inspection. The progress of each child should be watched and reported on by a suitable person in the area; each foster-home should be visited by an inspector within a month of the child's arrival and thereafter every six months without notice. A member of the children's care committee should be present at these visits. A local practitioner should give a medical report on the child every six months. All children with foster-parents or in homes should have pocket-money. After-care and the selection of suitable subsequent employment should be an essential feature in the care of children. The present control over voluntary homes should be extended, and their staffs should be more highly trained. Institutionalism should be avoided and every encouragement given to the development of the children as individuals. Large institutions should be split up, and no home should be a poor-house or an annexe of one. The children should go to a church and school outside the home. Unsatisfactory parents should be prevented from recovering children from care. Where a petition for adoption of a child is refused the court should have discretion to direct its removal to a place of safety. The maximum age of a child subject to care should be raised to 18. An advisory committee should be set up to advise the Secretary of State on the methods in use.

¹ Report of the Committee on Homeless Children. Edinburgh: H.M. Stationery Office, 1946. 9d.

PRESENTATION TO THE AMERICAN MEDICAL ASSOCIATION

A Gavel and Block made from the mulberry tree which grew in Charles Dickens's home in London now the site of B.M.A. House will be presented by the B.M.A. delegation to the American Medical Association on the occasion of its centenary celebrations in Atlantic City in the second week of June. The block is inscribed with these words

TO THE AMERICAN MEDICAL ASSOCIATION ON THE OCCASION OF ITS CENTENARY

AS A TOKEN OF GOOD WILL FROM THE BRITISH MEDICAL ASSOCIATION
THIS GAVEL AND BLOCK MADE FROM THE MULBERRY TREE
WHICH GREW

IN THE GARDEN OF CHARLES DICKENS'S HOME IN LONDON
WHERE THE BRITISH MEDICAL ASSOCIATION HOUSE NOW STANDS
JUNE 1947

Charles Dickens took Tavistock House in 1851 and the mulberry tree was in the garden; it was still there when the British Medical Association moved into Tavistock House in July, 1925. It has since then had to be cut down but the wood was preserved and out of this wood the gavel and block have been made. Dickens lived in Tavistock House for nine years. At one time Hans Christian Andersen stayed with him, and he describes how, 'On the first floor was a rich library with a fireplace and a writing-table, looking out on the garden, and here it was that in winter Dickens and his friends acted plays to the satisfaction of all parties. Dickens's nine years in Tavistock House formed "the most brilliant period of his career," to quote from an article in the *Journal* of July 18, 1925. It was in Tavistock House that he wrote or began to write *Bleak House*, *Hard Times*, *Little Dorrit*, *A Tale of Two Cities* and *Great Expectations*.

NEW ASPECTS OF INSULIN ACTION

Several interesting points came up in a more or less informal discussion in the Section of Endocrinology of the Royal Society of Medicine when the subject of new aspects of insulin action was introduced by Prof. F. G. Young from the biochemical side and by Dr. R. D. Lawrence from the clinical. One question which arose concerned haemochromatosis described by one of the speakers as a form of diabetes in which there was the pathological lesion and yet a distinct clinical entity was present. If ever there is a form of diabetes which can be attributed to failure of insulin production in the pancreas as Dr. W. G. Oakley pointed out it is the form associated with haemochromatosis and yet this type of diabetes has certain features which differentiate it from all other types. Many of the complications associated with diabetes are never or rarely seen in this condition. Retinitis is said never to develop, ketosis only seldom, a definite coma is extremely uncommon. Thus there is here one form of diabetes in which the pathology appears to be as straightforward as in any of the other varieties, and yet the clinical picture differs from the types customarily considered as being due to primary insulin deficiency. This aspect has not been investigated as much as it might have been.

Some 75 cases have been recently published in French literature and at King's College Hospital London there have been 20 or more. Dr. Lawrence described haemochromatosis as a severe type of diabetes caused by the undue disappearance of the island function of the pancreas owing to the haemochromatotic process. He said that certain of these patients did die in coma but it was true that the ghastly complications commonly met with in ordinary forms of diabetes—arteriosclerotic changes, retinal changes, kidney changes and gangrenous effects in the foot—were never encountered. While in America Dr. Lawrence had tried to interest the American Diabetes Association in the subject in view of their large field of observation, urging that they get together all their cases of haemochromatosis in particular examining those which had had the condition for ten years and finding out whether they were completely immune from the diabetic complications mentioned. If such immunity were established he said another cause for such complications should be sought. These complications

being absent in haemochromatosis there must be some other factor which caused them in ordinary forms of diabetes.

Carbohydrate Oxidation

The question of carbohydrate oxidation was another point raised in the discussion. Prof. Young suggested that there was no reason to suppose that carbohydrate oxidation could go on in the body as a process independent of the presence of insulin, and also of the anterior pituitary hormone, though the process nevertheless, was influenced by them. The suggestion was made a good many years ago, he said, that the action of insulin and the anterior pituitary hormone in this respect could be regarded as somewhat analogous to the action of the sympathetic and parasympathetic on the heart, in other words they did not initiate the process, which went on independently of them but they influenced it antagonistically. A further point arose out of Dr. Lawrence's observation that high blood sugar was the damaging agent on the islands of Langerhans in the pituitary-induced diabetes. This might be so, said Prof. Young, but he could not accept it as proved. He thought it possible that there was an inhibitory action of the hormones on the islands themselves, and that this in turn might cause degeneration when the islands were subjected to this action under conditions of high blood sugar.

In his view the high blood sugar was not the only damaging factor in these cases. The clinical condition of diabetes, and indeed other conditions might arise not necessarily from deficiencies of hormones directly, but from deficiencies of the enzyme system on which the hormones acted. There was a reason why there should not be congenital partial deficiency of the enzyme system. Recent work had suggested that probably there were inherited deficiencies as regards amino acid synthesis because of the deficiencies of the enzyme system originating in our ancestry. Prof. Young also referred to a case recently published in Brussels of a young girl who came for treatment for amenorrhoea, and during three years and a half observation developed acromegaly and then diabetes of a relatively mild type. After a further eighteen months she had a cerebral haemorrhage. Her sugar tolerance was abnormal, high and her fasting blood-sugar level abnormally low. It seemed that the islands of Langerhans had hypertrophied under the influence of pituitary secretion, when possibly some pituitary tumour had developed and had undergone a sudden dramatic remission.

IMPROVEMENTS IN ARTIFICIAL LIMBS
MINISTRY OF PENSIONS DEMONSTRATION

A demonstration of limb fitting which attracted unusual interest was given on March 25 at the Roehampton Limb Fitting Centre attached to Queen Mary's Hospital. It was arranged by the Ministry of Pensions Standing Advisory Committee—a committee set up by Parliament two years ago to initiate research work on improvements in artificial limbs and similar devices. About twenty amputees demonstrated the facility with which they could use their artificial limbs.

Sir Charles Darwin, chairman of the Advisory Committee, said that its work might be divided into research, invention and intelligence, and the research programme into the work done on legs and on arms. The main interest in the leg has been the search for minor improvements, for excellent artificial legs already existed. The arm, owing to questions of muscular control and mechanical adaptation, presented a more difficult problem, and it had been estimated that twenty years were required to attain maximum skill with an artificial hand. In the field of invention the committee had considered over 100 devices, of which some 24 had survived. So far as intelligence was concerned, the most important thing had been the contact which the committee had had with other countries. It was in regular correspondence with a similar committee in the United States and another in Canada, and had undertaken a mission in Europe. A statistical analysis of all artificial limbs cases in this country was being prepared. It was hoped that such a classification would help not only surgeons in arriving at the best methods and sites for amputation, but limb makers in ascertaining where breakdown was liable to occur.

Sir Walter Haward, Director General of Medical Services of the Ministry of Pensions, mentioned that there were now nineteen limb fitting centres in various parts of Great Britain. The influence of Roehampton was apparent in all of them.

Dr J. Craft of the research department at Roehampton, with the help of patients carried through an excellent demonstration. He began with a number of women amputees. Experiments had been made with different forms of corsets, each individually made from which an artificial leg could be suspended. It had been hoped that nylon would be of assistance, but it was a non-extensible fabric and did not wear well so that the corsets had to be made of a stronger material. The corset, which was shaped to the body, took the place of the leather belt formerly worn around the waist. Several women demonstrated the perfect fitting of the limb. One of them with a low knee amputation, was a skater. For men the usual support was a leather waist belt and a strap over the shoulder, but it had been possible to discard the shoulder harness in some cases and to attain a better gait.

The suction socket was the subject of experiment in this country after the war of 1914-18, but was dropped for various reasons. During a recent visit to Germany a remarkable number of suction sockets with no suspension at all were found among war amputees. The principle was a vacuum under the base of the stump. Here again a number of men, some of whom had had their new limbs only for a few weeks, demonstrated their ease in walking with this type of limb. The correct shape of the interior of the socket, Dr. Craft said was being worked out. In the new type the stump was pulled into the socket, whereas in the old type it had to be pushed in, which meant wrinkling around the perineum and the great discomfort.

In the case of the arms the fitting of the socket was of great importance. In the newest limb demonstrated there were nine different locking positions, and there was bisection in the mid-forearm instead of as usual, at the wrist, which was said to be an advantage. Dr. Craft also showed various examples of mechanical hands with attempts at finger control, but he said that the Ministry had come to the conclusion that mechanical appliances attached to the extremity were better for amputees than attempts to reproduce the five-fingered hand. A number of the men with these mechanical devices showed how they were able to perform their toilet, to use small tools, and to undertake drawing and typewriting.

Cineplastic and Krukenberg Operations

Prof. T. Pomfret Kilner then continued the demonstration by showing the results of the Sauerbruch cineplastic amputation and the Krukenberg operation, and some young Germans who had sustained upper limb amputations assisted him. Prof. Kilner said that he had entertained the hope that close co-operation between orthopaedic and plastic surgeons on the one hand and limb fitting surgeons and limb-makers on the other might assist the cineplastic procedure for upper-arm amputations in this country, in this he had been disappointed. There was a general impression that the skin tunnels made in this procedure gave considerable trouble and that the range of movement and motor action was so much restricted as to make the method useless for operating the artificial hand. The Ministry, however, had retained its interest in this subject throughout and inquiries were made of people who had seen such work in Germany and elsewhere.

The Sauerbruch cineplastic procedure consisted in the preparation of one or more skin lined tunnels in muscles which were used to activate the artificial hand. They might be made in the flexor or extensor muscles of the forearm or in the corresponding muscles of the upper arm. They gave sufficient sources of control both to fingers and to elbow in some cases, thus supplying both supination and pronation of the forearm. This operation did give the patient extra motor points. Occasionally the skin tunnel was made through skin only, not through muscle, and was used for suspension or retention of the prosthesis. In the Krukenberg operation the forearm was split longitudinally to produce pincers. The local skin of the forearm was raised to cover the outer digit of the pincers while the inner digit was covered by a skin flap taken from the adjacent wall.

As for the application of these procedures, in the through-wrist amputation the valuable movement of pronation and supination was employed to give flexion and extension of the fingers of the artificial limb, or movement of the jaws of the various gadgets which could be attached to the extremity. When the forearm had been amputated but the stump was long from elbow to extremity—17 cm. and upwards—either the Krukenberg or the cineplastic procedure might be carried out with satisfaction. If the amputation was shorter than 17 cm. the Krukenberg was not indicated but cineplastic procedures might be carried out, forearm flexors and extensors being used for movements of the fingers, while the shoulder harness might be employed to give pronation and supination to the prosthesis.

Both procedures appeared to give stumps capable of resisting ordinary wear and tear, but in Germany no cineplastic case was observed performing heavy manual work. Only clerical work or work calling for fine finger movements was done. The Krukenberg procedure was essentially one for the double amputee, the man with one good limb was unlikely to concentrate on the training of the Krukenberg stump. He saw in Berlin a Krukenberg case of six years standing, and the man was able to lift a 70 lb. (32 kg.) weight, as well as to play tennis and shave. With the cineplastic device it was possible also to pick up matches with forceps, take coins out of a purse, fasten buttons, and so on. It was estimated that from 6 to 8 months was required for operation and training, but where a good Krukenberg procedure could be performed it gave the stump a greater usefulness than any other method. The appearance, like that of artificial limbs in general, was odd, but not repulsive.

A number of young Germans who had undergone operation in their own country then showed what they could do with the cineplastic and Krukenberg devices. One of them when asked why he elected to have the Krukenberg, replied that he wanted to be independent of all types of artificial limbs and other gadgets, but in general the frequency of the Krukenberg procedure was attributed to the lack of artificial limbs, which was very apparent in Germany. It was admitted that the Krukenberg limb caused fatigue pains in the muscles to develop rather quickly during sustained employment.

ESKIMO DENTITION

Dr. P. O. Pedersen, the distinguished Copenhagen odontologist, gave an interesting account to the Odontological Section of the Royal Society of Medicine on April 14 on three expeditions which have gone to Greenland in recent years to investigate the teeth of the Eskimo. On the eastern shore of Greenland Danish colonization and white contact began only some 50 years ago, but western Greenland has been colonized for more than 200 years, its harbours are the doorsteps of Western civilization, and here the natives have settled in permanent dwellings and have drastically changed their dietary habits. At the beginning of the present century the calorie requirements of the West Greenland population necessitated only some 17% of imported food. The latest figures suggest that over 50% of the food is imported. The consumption of sugar in West Greenland has reached or surpassed the high levels of countries like Denmark and the United States. All this is reflected in the state of the teeth of the population. One of the main subjects of study of the expeditions (which were undertaken under the auspices of the Royal Danish Colonial Institute and the Danish Dental College) was the extent of dental caries. An examination of over 500 Eskimo skulls found in an old burial place revealed only two carious teeth out of 5745 teeth examined and it was not entirely beyond doubt that the skull in which these carious teeth were found belonged to the period before the white invasion.

It can be said with a fair degree of confidence that there was no caries in Greenland in pre-Danish times. To-day caries is a common disease among the Eskimo population. Even in the trading posts of eastern Greenland where white contact dates back only for half a century caries has risen to a considerable level and in western Greenland which has known the white man and his ways for a far longer period, the incidence

alarming. More than 50% of the deciduous teeth of the Eskimo children at the trading stations in western Greenland are carious. The incidence is as high as in the old countries of northern and western Europe perhaps even higher. In the villages away from the trading centres and harbours only 5% of the people show evidence of caries. The younger adults are far more frequently affected than the old.

Teeth and Ethnography

Teeth, small and insignificant in themselves as Dr Pedersen said are big with meaning. They are at once the most plastic and most conservative of structures. A close study of dentition is useful not only in indicating social change but in interpreting anthropology and ethnography, and among the still partly unsolved problems of ethnography is that of the origin and migration of the Eskimo. For example shovel shaped incisors are almost universally found among the Eskimo—a characteristic which they share with Mongolian stocks in eastern Asia, but their cusp numbers and occlusal patterns resemble more closely those found in fossil apes than those in any racial or ethnic group known. Enamel extensions from gingival margins are normal among the Eskimo of Greenland and are frequently present to an extreme degree. Supernumerary roots are also frequent. Disturbances of enamel and dentine formation are rare. Some women show a form of dental fluorosis caused by mixing a certain amount of creolite powder into their snuff, and the fluorosis is transmitted to their children. On the other hand gingivitis which is widespread is found with greater frequency and to a more severe degree among men than women—a circumstance put down to the fact that men are more addicted than women to chewing a tobacco quid. Loose teeth are met with in the primitive Eskimo only under very special conditions, such as the loss of the opposite tooth, thereby depriving the other of function.

One characteristic of Eskimo nurture remarked upon by Dr Pedersen (though he did not elaborate its possible bearing upon dentition) is that children frequently remain at the breast until they are six or seven years old. Indeed in the primitive community if the child could not be suckled by the mother or some other woman it would perish. Dr Pedersen said that he had actually seen a boy of six who was still at his mother's breast, but had in the meantime acquired the art of smoking cigarettes.

Nova et Vetera

THE ROTUNDA HOSPITAL BUILDINGS

The Rotunda Hospital. Its Architects and Craftsmen. A study by C. P. Curran with photographs by E. Phyllis Thompson. At the Sign of the Three Candles, Fleet Street, Dublin. 10s. 6d.

Moved by the bicentenary of the Rotunda Hospital, Dublin, Mr C. P. Curran has composed an agreeable essay on the history of the hospital in the 18th century from the standpoint of the arts. In this he has had the collaboration of a skilful photographer, Miss E. Phyllis Thompson. The craftsmen with whom he is mainly concerned are not unworthy to stand beside those others—physicians and scientists—of whom Dr Kirkpatrick has written in his *Book of the Rotunda Hospital* the authoritative work to which this essay is a footnote. Dr Ninian Falkner, Master of the Rotunda, expresses his thanks in a foreword to author and illustrator for having carried out this work as their tribute to the memory of Bartholomew Mosse.

On March 15 1745 Dr Mosse, then a young surgeon and obstetrician of philanthropic turn, opened his private lying-in hospital for poor women, which led directly to the establishment of the Rotunda and was the first charity of its kind in these islands. From the beginning Mosse mixed his own relish for the fine arts with every scheme for the development of his hospital using assemblies, balls, concerts, card parties, and lotteries to catch the fashionable public. He chose the most eminent architect in Ireland for his building, and the most distinguished sculptor available to embellish its corridors and gardens. The foundation stone of the new building was laid on July 9, 1751, and in 1757 the first patients were received.

The architect was Richard Cassells, a German born at Cassel in Hesse. Some of Mr Curran's study is devoted to answering questions which arise concerning Cassells's work. How comes it that a German architect born about 1690 should be so detached from the baroque of his period? Why should he build in a specially severe form of Palladianism? And why should he mix Dutch elements with his Palladianism? In the hospital accounts the main craftsman in plaster is described as both a statuary and a stucco man, his style is distinctive and unlike anything else in Ireland, but Cramillon was not the only stuccodore engaged in or about the hospital—chief among his followers was Robert West.

The round room or rotunda, whose name has gradually passed to the hospital itself, was built by John Ensor in 1764. Though Ensor built no other public building his share in the domestic architecture of Dublin, Mr Curran says, is even more extensive than that of Cassells; he left his mark on the city in the characteristic layout of its squares. The last stage in this building history began in 1784. Richard Johnstone was appointed architect of the new works and he designed the present Cavendish Row frontage. From the outset Dr Mosse planned his New Gardens as a place of fashionable entertainment in support of his hospital, and the proceeds from this venture were very considerable. The direction of the music as of everything else, lay in Mosse's hands, assisted by his nephew, and Mr Curran enters with relish into details of some of the programmes and performances. His Appendix of Craftsmen is followed by a list of 18th century musicians who helped the project. Miss Thompson's photographs are grouped at the end of the book, except that of the bust of Bartholomew Mosse (1757). The frontispiece is from an engraving of the exterior of 'The Lying-in Hospital and Rotunda, Dublin' dated 1830. Mr Colm O Lochlainn, as typographer, has produced a shapely volume, pleasing to the eye.

Preparations and Appliances

TROLLEY FOR GAS CYLINDERS

Dr G. O. COWDY, The Old Manor, Salisbury, writes

In this large mental hospital the wards are separated by considerable distances, which raised the problem of a convenient apparatus for the conveyance of oxygen and carbon dioxide cylinders from one ward to the other. The difficulty was made more acute by the fact that in many cases the wards are only joined by gravel paths over which it would be almost impossible to push any ordinary four-wheeled trolley. The problem was put to our chief engineer, Mr F. Baum, who has designed a two-wheeled trolley. This has proved so successful that I thought the design might be of general interest.

Basically it is like the hand trolleys used on railway platforms. Two hollows in the base take the lower ends of the cylinders, which rest in grooves in the cross pieces of the trolley. Leather straps secure them near the upper ends and prevent them from falling forward. The two main wheels are rubber-tired and a small wheel at the front of the base allows the trolley to be moved about within the ward in an upright position. The sketch made by a patient shows the general construction.

My thanks are due to the medical superintendent, Dr S. E. Martin, for permission to record the details of this apparatus.

Reports of Societies

THE NURSING SHORTAGE

At a joint meeting of the Society of Medical Officers of Health (Fever Group) and the Medical Superintendents' Society (London and Home Counties Branch) held at B.M.A. House on March 14, Dr WILLIAM GUNN, president of the Fever Group, took the chair. A discussion on the Nursing Shortage was opened by Dr H. STANLEY BANKS, president of the London and Home Counties Branch of the Medical Superintendents' Society, Dr E. B. BROOKE (Surrey), Dr O. W. S. FITZGERALD (Herts), and Dr W. F. T. McMATH (Willesden). At the request of the meeting, the points raised in the discussion were embodied in a memorandum, drawn up by the openers, which is here summarized.

Character and Incidence

There are said to be more nurses in the country to-day than ever before. This may be so for nurses are now employed much more than formerly in attractive jobs outside hospitals. Further, the shorter hours now worked in many hospitals necessitate an increase of some 10 or 12% in the number of nurses staffing a given number of beds. It is in the local authority hospitals, the special hospitals and the smaller voluntary hospitals that the acute shortage exists. Most of the local authority general hospitals in London have had to close down about half their beds, and the fever hospitals even more. This affects thousands of cases and also the fever hospital training of medical students and graduates.

The great London voluntary hospitals are said to have no shortage of nurses. This is doubtless, partly due to the inherent attractiveness of these hospitals. These discrepancies in staffing as between different kinds of hospitals have been greatly exaggerated since the Rushcliffe scales of salary were introduced in 1943. The Rushcliffe policy of uniformity of salary scales for all hospitals, regardless of their varying appeal to prospective nurses, is a major factor in the shortage.

The average female population from which nursing recruits may be drawn dropped from 361,000 in the quinquennium 1922-6 to 301,200 in the quinquennium 1942-6, a decrease of 16% in 20 years. Owing to the continued low birth rate during the years 1930-45 the available population is likely to decrease further, and for the next few years the female population available as potential nursing recruits will be some 20% less than that available a quarter of a century ago.

Alternative Employment

From this diminished female population the proportion attracted to industry, to the Services and to clerical and administrative work has increased as compared with that entering hospital nursing. The reasons usually advanced for this include higher wages, shorter hours, and home life or unrestricted private life. On the other hand, the nurse's life has been represented for years as one of genteel poverty, hard domestic work, long hours, and semi-monastic existence. In fact remuneration (except for student nurses) has been substantially increased, ward orderlies are being recruited for the more menial tasks, there is minimal interference with the nurse's private life and any qualified nurse may live out. These facts should be publicized in every possible way.

The shortage of nurses at present is one mainly of entrants to the profession. All our observations indicate that, in London at least, the foremost reason for this shortage is the low salary offered to nurses in training. The Rushcliffe Committee rightly considered the nurse's prospects after training to be more important than an attractive salary during training. But the salary of trainees was fixed at figures which are now below the economic level, and require subsidy from private sources, at least in London, if a reasonable standard of existence is to be maintained.

Salary Scales

The Rushcliffe salary scales for student nurses, although slightly increased since 1943, have been rendered out of date by the rising cost of living and by the "Hetherington" scales for female domestic staff and the "Mowbray" scales for male

domestic staff. The "Mowbray" scales recognize the principle of a "loading" of about 15% for London. This principle should certainly be applied to nurses' remuneration.

Weekly Wages of certain Resident Staff (plus board, lodging and laundry)

	£	s	d
Student Nurses, 1st year	1	1	2
" " 2nd year	1	5	0
" " 3rd year	1	8	10
Staff Nurse (Fever Trained) 1st year	2	2	4
" " (General Trained) 1st year	2	6	2
General Trained Student Nurse (Fever)	1	14	7
Ward Orderly	2	9	6
Domestic Assistant	2	7	6

A student nurse has to work and study for at least five years before she attains to the remuneration of a ward orderly or of a ward maid aged 18 over whom she is set in authority. When superannuation, insurance and other necessary contributions are deducted she has some 17s or 18s a week on which to clothe herself, travel, entertain herself on her day off, meet personal items of expenditure, buy textbooks, pay examination fees, etc.

It is clear that a higher salary (or training allowance) for student nurses is needed in those hospitals which cannot now attract recruits. It should not be applied uniformly everywhere for that would not cure the maldistribution of student nurses that now exists. In order to preserve the balance higher salaries—for example, £100 plus emoluments—are needed in the less attractive hospitals and in London there should be a loading of 15% to 20% as in the Mowbray scales.

Formerly the sense or spirit of vocation was one of the most powerful motives in the recruitment of nurses. This motive should be fostered in recruitment especially among senior school girls. In these times of economic stress however it is useless to rely upon the vocational motive alone without at the same time offering reasonable monetary inducements.

The Gap in Training

Many potential nurses are lost because their interest is not sustained between the school leaving age and the age of entry as a student nurse. To obtain adequate numbers of suitable educated nurses education authorities will have to set up pre-nursing training schools for suitable girls. A small maintenance grant would be necessary in most cases, especially in London. Subjects of instruction should include mothercraft, nursing, anatomy, physiology, hygiene, dietetics and domestic science. Visits might be made to day nurseries and hospitals and in the last year of the course the girls might be fully employed in day and residential nurseries. An admirable scheme of this sort is in operation in Dundee.

Basic Practical Courses

The regulations of the General Nursing Council are too exclusively directed towards the enhancement of the professional status of the nurse and too little towards the production of sufficient practical nurses to care for the sick. The number of nurses required is so large that it is wasteful to try to train them all to undertake the most highly skilled work. The hospitals demand large numbers who need no more than the basic skills of practical nursing and only relatively few with an advanced theoretical training. But the former group must be thoroughly trained in practical bedside nursing must be accorded the status of nurse and not assistant nurse and have remuneration adequate to their status. The regulations of the General Nursing Council should be re-designed to this end, and the Council should be responsible for ensuring that its regulations for training are compatible with an adequate flow of recruits to the profession.

A shortened practical basic course of two years' duration should be undertaken by all nurses. This should include three or four months' whole-time theoretical training in elementary physiology, hygiene and dietetics but the main emphasis should be on bedside nursing. The examination should be entirely practical and should lead to qualification as an enrolled nurse. The practical training should be taken in any general or special hospital of suitable size. The status and remuneration attached to the grade "enrolled nurse" must be sufficient to attract the large numbers who would elect to remain in this grade. For those who wish to rise to the rank of ward sister there should

be one year's higher training followed by a theoretical and practical examination leading to qualification as a State Registered Nurse. The minimum age of enrolment as a nurse should be 20 years, and of registration 21 years.

Foreign Trainees

The reduction in potential recruits and the great demand for female labour in industry point strongly to the need for foreign immigrants sufficiently educated to train as nurses. There are still large numbers of suitable young women on the Continent willing and anxious to come to Britain for such a purpose. Trained nurses, whether of foreign or national origin, are never likely to become a burden on the community through unemployment but are likely to remain as permanent assets. The employment of part-time nurses, on the Gloucestershire model or otherwise, should also be encouraged.

TUBERCULOSIS OF BONES AND JOINTS

The Spring Meeting of the British Orthopaedic Association was held at University College, Exeter, and the Princess Elizabeth Orthopaedic Hospital on April 25 and 26 under the presidency of Mr GEORGE PERKINS, M.C.

A symposium on the surgical treatment of tuberculosis of bones and joints was opened by Mr G. R. GIRDLESTONE, who stressed the importance of strict criteria in the estimation of results and remarked upon the rarity of dissemination by operation if well timed and if preceded and followed by immobilization. He condemned concern with the local lesion to the exclusion of the tuberculous patient as a whole, and emphasized the importance of prolonged care after discharge from hospital. He attached much importance to serial estimations of the erythrocyte sedimentation rate in assessing progress.

Mr NORMAN CAPENER reviewed tuberculous disease of the spine in 351 cases, emphasizing the difference of the disease and response to treatment in children and adults. In the first 15 years lower thoracic (dorsal) disease predominated, afterwards lumbar. 177 cases were treated by arthrodesis, with no mortality in the first 9 months, the tibia providing the graft fractured only once in contrast with the experience in traumatic cases. He thought that the key to the treatment of thoracic spinal disease might be treatment of the abscess.

The Hip-joint

Mr M. C. WILKINSON, speaking of tuberculous disease of the hip joint, had found an unstable hip in 22 out of 50 treated conservatively alone. The value of operation was measured by its success in securing stability and in safeguarding against recurrence. His operative mortality in 75 cases was early 2 and late 2. He had particularly practised osteotomy with medial displacement of the distal fragment but lately he had supplemented this with an extra articular femoral graft slid along the upper border of the neck. Operation was performed in the presence of active disease after the patient's resistance had been raised by conservative treatment and the re-ossification which ensued might be ascribed to auto-inoculation or to the decompression of tuberculous foci. Bony ankylosis might take as long as two years though the hip usually became quite stable before this. Mr Wilkinson's view that displacement osteotomy was often of great value in the treatment of tuberculous hip-joints was supported by Mr D. WAINWRIGHT who showed how a combination of osteotomy and an ischio-femoral graft produced rapid bony ankylosis and he showed also the result of supplementing long oblique osteotomy by traction so that not only was apparent lengthening produced by angulation but also real lengthening by distraction. Dr J. DELCHEF advocated early arthrodesis while the disease was still active. Mr H. A. BRITAIN considered that the hip demanded different treatment from the other joints of the lower limb because it could be short-circuited from weight-bearing by ischio-femoral arthrodesis.

Mr J. P. CAMPBELL reviewed 89 cases of tuberculosis of the knee-joint treated at Harlow Wood Orthopaedic Hospital. A quarter of the cases were purely synovial in type. Some cases with osseous lesions developed a serviceable range of movement. Intra-articular arthrodesis resulted in bony fusion much more quickly in cases of more than three years standing than in more recent cases similarly treated. Bone-grafting operations

were reserved for adults in whom they supplemented intra-articular arthrodesis, or were used to promote bony fusion where resection of the joint alone had failed. Dr J. MORTENS, reviewing 76 cases, concluded that arthrodesis should be postponed to the age of 13 or 14 if an epiphysis was involved, but that otherwise 9 years was not too young an age for the operation.

In considering 118 cases of tuberculosis of the foot and ankle Mr B. L. MCFARLAND contrasted the very good though slow response to conservative treatment in children with the frequently poor result in adults in whom dissemination or sinus formation frequently determined amputation. Conservative treatment with or without arthrodesis might be indicated in some younger adults but in the older patient with tuberculosis of ankle or tarsus amputation was not merely justifiable but often imperative.

Mr J. A. CHOLMELEY reviewed 94 of 100 cases of tuberculosis of bones and joints of the upper limb treated in the Royal National Orthopaedic Hospital (Country Branch) in the years 1924-46. The parts affected were shoulder in 36 cases, elbow in 25, wrist in 22, metacarpals and phalanges in 10, and humeral shaft (local lesion) in 1. All patients received conservative treatment supplemented in a few by operation. Arthrodesis of 8 shoulders in adults, excision of an elbow and partial excision of another with drainage for secondary infection, local excision of the local humeral lesion. Arthrodesis of the shoulder, which was often determined by occupation, gave good results in adults, with bony fusion in every case whereas recurrence took place in 3 of the shoulders not operated upon. Two elbows including that excised showed recurrence. There was none in the wrist, metacarpal, phalangeal or humeral cases.

Sir REGINALD WATSON JONES concluded that tuberculosis of bones and joints presented from the viewpoint of treatment two diseases—that in children and that in adults. Both demanded conservative treatment in children; this sufficed but in adults it should often be supplemented by surgical fusion after quiescence of the disease. The position was reversed in the case of the spine which should be more often arthrodesed in children and more rarely in adults because in children conservative treatment of dorsal disease left an unstable spine with increasing deformity whereas in adults lumbar disease nearly always led to spontaneous ankylosis.

Smith-Petersen's Cup Arthroplasty

Dr M. N. SMITH-PETERSEN, who was elected an Honorary Fellow of the Association, gave a lucid account of his operation of cup arthroplasty of the hip illustrated by slides and films. The restoration of shapely smooth cartilaginous articular surfaces was convincingly demonstrated. Mr W. ALEXANDER LAW had found that some 80% of Dr Smith-Petersen's cup arthroplasty operations gave a result satisfying to patient and surgeon, but it was essential that the former should co-operate actively with exercises for two years.

Other Communications

Mr H. G. S. KORVIN concluded from radiological evidence that the pathological changes in pseudocoxalgia were those of ordinary aseptic necrosis and that destructive changes were the biological consequences of the mechanical damage of weight-bearing. Mr F. C. DURBIN had followed up 525 cases of sciatica and selected 147 cases of sciatica with neurological signs treated without operation. Of 123 receiving plaster jackets 19 patients were relieved or cured. Mr G. BLUNDELL JONES had investigated the penicillin content of the synovial fluid of knees with open war wounds 48 hours after a single instillation of 100,000 units. He found retention in adequate concentration provided the effusion was not diminishing. Absorption of effusion led to more rapid disappearance of intra-articular penicillin but at this stage penicillin was no longer needed in the joint. Penicillin given intramuscularly was not found in adequate concentration in the synovial fluid of the joint if completely immobilized.

Mr A. L. EYRE-BROOK showed a patient with bilateral cneplastic forearm stumps and two patients with Krukenberg forearm stumps. The success of the operations (performed by German surgeons) was undoubted, and function appeared particularly good in the Krukenberg stumps on account of the preservation of sensation.

Correspondence

Tudor Edwards Memorial

SIR,—Subscriptions are invited to a fund for the establishment of a memorial to the late Mr Arthur Tudor Edwards, M.D., M.Ch., F.R.C.S., who died on August 25, 1946, at the age of 56.

The remarkable progress of chest surgery in this country is in large measure due to Tudor Edwards's work. His pioneering in this branch was in the main the chief stimulus to its expansion. His singleness of purpose, and the high standard which he set for himself and all those who worked with him, raised a small but important branch of surgery to its present position as one of the great surgical specialties. As the result of this development, men and women have been restored to life and health for whom previously medical science offered no effective aid. Tudor Edwards literally devoted his life to his work. He was unsparing in his service to his patients in all walks of life and many came to him from other countries. On the outbreak of war, in addition to his other work, he undertook the organization of thoracic surgery for the Emergency Medical Service of the whole country and for the Army and Royal Air Force. He carried this heavy burden throughout the war despite the gravest warnings and with the full knowledge that his life thereby would be shortened. One of his greatest contributions was his training and inspiration of younger men who came to him from all parts of this country and from abroad.

There could be no better memorial than to continue this work which was so close to his heart: the training of young surgeons to build on the foundations he so securely laid. It is proposed that a Travelling Scholarship shall be founded in Tudor Edwards's name to enable suitable candidates to study thoracic surgery in special centres. This also will fulfil an urgent national need. For this purpose, a capital sum of at least £10,000 will be required. The Royal College of Surgeons and the Royal College of Physicians have agreed to administer the fund and carry out the conditions of the Trust. Donations and subscriptions under deed of covenant should be sent to The Hon. Treasurer, The Rt. Hon. Lord Courtauld-Thomson, K.B.E., C.B., Brompton Hospital, London, S.W.3.—We are, etc.,

Calories

SIR,—The claims that we are seriously short of calories are, at least exaggerated but it is unfortunate that Government spokesmen should continue to claim that the average calories per head per day are in the neighbourhood of 2,900. It is fully explained in "Food Consumption Levels in the United States, Canada, and the United Kingdom" that these figures are derived from estimates of the amounts of food imported and produced in the country. The surveys of the Ministry of Food are made on representative families. They show that the average per head ranges from 2,300 to 2,400. Meals taken outside cannot raise the total to more than 2,650. The gap between the amounts that we can get and 2,900 is only too obvious.

The calculations of Bransby and Magee in the *British Medical Journal* of April 19 (p. 525) show how difficult it is to reach the standards of the League of Nations without excessive consumption of potatoes and exchange of points for B.U.s, and 2,900 per head per day as an average for the whole population, is well above this standard. The figures given by J. C. Drummond (*Sth. med. J.*, 1946, 39, 18) show that the average 2,273 calories consumed in 1944 amounted to just under 97% of requirements: very similar figures were found in similar surveys made before the war.

With the larger amounts now eaten outside the home the average in representative families must be well up to require

ments. But that does not justify the claim that we are getting as much as 2,900 calories, nor does it mean that bread rationing does not make it difficult for some individuals to get enough calories—I am, etc.,

JOHN MARRAS

"Costoclavicular Compression"

SIR,—The paper by Prof. E. D. Telford and Mr. S. Mottershead (March 15, p. 325) raises again the question of the cause of disappearance of the radial pulse with certain positions of the arm in some cases of cervical rib. Are the effects on the main artery of the limb mechanical, due to its compression by the scalenes as suggested by J. B. Murphy in 1906 and Wingate Todd in 1911 or to its being squeezed between the clavicle and the rib as claimed by K. C. Eden in 1939 and supported by Wilfred Trotter? Are they due to the effect on sympathetic nerve fibres in the lowest trunk of the plexus produced by stretching over the rib as Wingate Todd postulated in 1913 and Telford and Stopford elaborated in 1930? Or are they, as Telford and Mottershead have now recently suggested, caused by the two heads of the median nerve gripping the artery when the arm is pulled downwards? Most surgeons who have had experience of these cases will probably agree with Telford and Mottershead that there is no one cause common to all cases. These writers have shown that forcible depression of the shoulder widens rather than narrows the costoclavicular interval but lest it be thought that costoclavicular mechanical compression cannot therefore be a cause, we would refer to a recent case which came under our observation.

A boy aged 15 was seen in September, 1946, with a pulsating swelling above the inner end of the right clavicle which proved to be the subclavian artery rendered unduly prominent as it passed over the lower splayed out end of a complete cervical rib. There were no symptoms and it was decided to leave well alone. The boy then began work on a machine which involved much use of his right arm and soon found that from time to time the arm began to ache. He was re-examined, and it was found that elevation of the shoulder obliterated the radial pulse. It was clearly demonstrated that this was due to the inner end of the clavicle moving upwards and slightly backwards towards the large cervical rib and compressing the artery at this level. At operation this was verified, there was an aneurysmal dilatation of the artery with some perianeuritis at this site. Removal of the lower end of the rib freed the artery from compression by the moving clavicle.

Our object in referring to this case is to emphasize that costoclavicular compression of the subclavian artery may occur from upward and backward movement of the arm and in certain cases such movement may be as effective in obliterating the main artery as may depression of the shoulder girdle in other cases.—We are, etc.

The Vole Bacillus

SIR,—Your timely leader (May 31, p. 770) on the recently published monograph on the "Murine Type of Tubercle Bacillus" (the vole acid fast bacillus) by A. Q. Wells, the discoverer of the vole bacillus vaccine merits the closest attention of all interested in the subject of active immunization against tuberculosis. Having last year paid a visit (sponsored by the Public Health Committee of the County Borough of Luton) for whom I acted as consultant physician for tuberculosis and diseases of the chest and to whom I am greatly indebted to the Scandinavian countries I had the opportunity of studying for myself the work done there. The enthusiasm for B.C.G. in Norway, Sweden and Denmark was widespread but nothing I saw impressed me more than the work of Prof. Arvid Walleröf of Stockholm who has certainly been the pioneer of B.C.G. vaccination in Sweden where he began his work at Gothenburg in 1926. His confidence in the value of B.C.G. persists although it is pertinent to note with reference to your leader that he himself urged that it would be of greatest value if we

in this country were to use the vole vaccine. He gave me the impression that he believed it would eventually supersede BCG.

I think there is good evidence for the belief that both methods of inoculation (a) are harmless to humans (b) increase resistance to tuberculosis (c) are of value only in tuberculin negative subjects. While it is true to say that BCG has stood the test of time in many countries and its harmlessness has been established by its practical application on a large scale in many parts of the world nevertheless there is good evidence that the vole bacillus has the following advantages over BCG: (a) it is apparently a more potent immunizing agent, (b) its virulence is more stable (the varying virulence of BCG in Norway, Denmark, and Sweden was significant and I was told on more than one occasion that some of the strains were losing their virulence), (c) there is reason to believe that tuberculin allergy following vaccination with it was greater and occurred earlier than that following BCG.

The time seems surely to have arrived when an authoritative body such as the Medical Research Council should institute a clinical trial with control experiments for statistical purposes of what they regard as the most effective method of tuberculosis vaccination. We may then be able to fill in the gaps which Continental and other workers, often through lack of opportunities, have omitted.

One final word you say in your leader that the multiple puncture method is now considered the best method of inoculation with BCG. This is contrary to my own impressions for wherever I went the intracutaneous method devised by Wallgren was, when correctly performed, regarded as the quickest most valuable and practical, and it certainly afforded a more accurate measure of the dosage. Certainly the multiple puncture method with the Birkhaug-Rosenthal instrument seemed to meet with little favour in most of the clinics I visited—I am, etc.,

London W 1

PHILIP ELLMAN

Nicotinic Acid Tolerance Test

SIR—In their excellent paper (May 17, p. 672) on their nicotinamide saturation test Drs P. Ellinger and S. W. Hardwick note that, in pellagrins, there is a markedly low response on the administration of nicotinamide but that this response can be increased, in pellagrins only, by the administration of methionine.

In therapeutic tests with nicotinic acid (the precursor of nicotinamide) in hepatitis cases it was noted that the usual vasodilatory response seems to be very much delayed. To investigate this a nicotinic acid tolerance test has been devised in which the patient or control takes 200–300 mg nicotinic acid orally. If there is no response in 15 minutes, further 100 mg is given every 15 minutes until the flushing of the face is reported. The work has not yet reached the stage of publication. However the preliminary results noted on over 120 cases seem to endorse and also amplify Ellinger and Hardwick's findings.

The following conclusions seem to be justified so far:

(1) In 'normal' subjects—that is, in patients and controls with out evidence of hepatitis—there is a response on 200–300 mg, so much so that much higher values justify further investigations of the liver functions. Two unsuspected cases of chronic amoebiasis were so detected.

(2) The tolerance seems to be within normal limits in cases of sprue, congestive heart failure (only early cases could be tested), chronic mild cholecystitis, and in one case of liver secondaries.

(3) There is a marked, increased tolerance in cases of infective hepatitis (with or without jaundice), infective mononucleosis, homologous serum jaundice and in subacute and chronic amoebiasis. The tolerance figures range between 500 and 1,200 mg. No cases of cirrhosis or pellagra were available for the test so far.

(4) The tolerance seems to be proportionate to the inflammation of the liver parenchyma, as judged by gravity of the condition of the patient and size and tenderness of the organ, but there seems to be no connexion between the deepness of the jaundice and the tolerance figure.

(5) Tested only in generalized inflammatory conditions, the tolerance seems to be more sensitive than the usual liver functions tests. The Takata-Ara reaction will be hardly positive (+) under a tolerance figure of 1,000 mg, and signs of a deranged carbohydrate metabolism are rare under a tolerance of 700 mg. The test is useful

as a ward test, and is of some help in the diagnosis of obscure epigastric symptoms especially in the exclusion of chronic amoebic hepatitis in soldiers returning from overseas. Like any ward test or any test it is probably not perfect and does not give more than a useful hint.

(6) The same tolerance values are obtained if the test is repeated eight hourly. There is, however, a sudden decrease in the tolerance when recovery sets in, and this change can be quite dramatic—e.g., after 1–2 emetine injections.

Here a word of warning must be given. Massive doses of nicotinic acid (200 mg t.d.s.) combined with high protein diet (shakes of household milk and dried eggs or soya flour) seem to have some therapeutic effect in cases of infective hepatitis. If higher doses are given, or the test is repeated daily, thiamin and riboflavin (6–8 mg each) should also be given. In one case, myself acute sprue symptoms were provoked by repeated nicotinic acid tests amounting to 1,800 mg daily for 5 days. The symptoms quickly cleared up on massive doses of riboflavin.

In trying to interpret the mechanism of the increased nicotinic acid tolerance one is inclined to assume that the compound is either retained by the liver for the purpose of utilization in repair, or else its release by the liver is delayed by the lack (or increased utilization) of sulphur containing amino acids—Ellingers and Hardwick's 'methyl donors'. Ellingers and Hardwick's findings seem to support the latter assumption. They noted increased urinary output of nicotinamide methochloride on the exhibition of methionine in pellagrins, and no doubt the liver parenchyma suffers in that disease. On the other hand the fairly constant tolerance figures in the nicotinic acid test, and the constant urinary output of nicotinamide methochloride in the saturation test, do not confirm the assumption that the delay in passing the liver is caused by the lack of 'donors' only, if this was the case one would expect daily increasing tolerance. Probably much more work will have to be done on the subject before the role of the liver (and that of the kidney) in the nicotinamide metabolism will be understood—I am, etc.

Physical Therapy of Mental Disorder

SIR—A careful perusal of Dr D. W. Winnicott's paper (May 17, p. 688) has led me to the conclusion that he intended it to be provocative rather than wholly serious. Dr Winnicott's main objection to physical methods of treatment in psychiatry is that they are 'unscientific,' and he states, 'Much of the objection to convulsion therapy would disappear if the mechanism by which results are obtained were understood. Would Dr Winnicott, on similar grounds, say fifty years ago have withheld digitalis in a case of cardiac oedema or quinine in a case of malaria, or would he to-day withhold malaria fever in a case of general paralysis?'.

The practising psychiatrist of to-day must answer the question: Shall I allow this melancholic patient to remain indefinitely in acute depression with all its mental suffering not excluding risks of suicide or death from inanition due to refusal of food or from aspiration pneumonia due to tube feeding? Shall I give him ECT and restore him fit and well to his family in approximately six weeks? Or again, when faced by a case of acute delirium (manic or melancholic), shall the psychiatrist withhold ECT and assure the relatives that death is almost inevitable, or shall he give ECT with at least a three to one chance of success? Or again, should a psychiatrist subject an anxiety neurotic mother to months of psychological investigation with the almost unbearable strain of her symptoms on her children and husband, not to speak of risks of suicide or infanticide, or should he not rather prefer to restore her to complete happiness and health with five or six convulsions?

A young man is suddenly stricken with an acute schizophrenic illness. The 'scientific' psychiatrist must tell his father that nothing can be done and that almost inevitably the patient will rapidly drift into a condition of profound dementia. The 'empirical' psychiatrist will immediately adopt treatment by insulin shock with at least a fair prospect of success. In cases selected for leucotomy (almost always mental hospital cases where both insulin shock and ECT have failed but where the residual mental capacity appears reasonably good) the choice

I-S-O-GEL, a granular preparation of certain dried mucilaginous seeds, has the property of reproducing the normal stimulus to intestinal peristalsis by increasing the intestinal bulk through absorption of water in the alimentary canal

I-S-O-GEL contains no purgatives and is a purely natural laxative with a smooth mechanical action, specially suitable for the constipation of diabetes

It is valuable also in mucous colitis, dysentery, hemorrhoids, and intestinal flatulence. After the performance of colostomy, I-so-gel gives excellent results by solidifying the faeces

Ribena therapy in infant welfare

The administration of vitamin C to infants has become a routine feature in child welfare. During the war, scarcity of orange juice was counterbalanced with excellent results by the use of other sources of the vitamin natural to Britain, notably blackcurrant juice, which the Ministry of Food approved as a particularly satisfactory alternative.

It is noteworthy that Ribena can be employed with advantage as a means of supplying natural vitamin C to infants from as early as the fourth week onwards, being quite free from cellular material, it cannot upset the most delicate digestion.

During the growing period generally, the vitamin C requirement is known to be much higher comparatively than during adult life, so that an accessory supply, as provided by 'Ribena,' is obviously of great benefit to children.

Ribena is standardised at not less than 20 mg ascorbic acid per fl oz

again between the "scientific" method of doing nothing, thereby condemning the patient to lifelong incarceration, and the "empirical" method of leucotomy with its reasonable prospect of success

Surely Dr Winnicott cannot defend many of his statements as being either "accurate" or "scientific"—e.g., "convulsion therapy inevitably leads away from the psychological approach to a biochemical and a neurological one" This I submit is a highly controversial statement My own experience is that all these physical methods require for their correct use accurate case histories, precise observation of their effects, and a sound psychological insight into the patient's mentality both before and after treatment To delegate these treatments to junior medical officers in a sort of hit-or-miss fashion is of course *bad psychiatry* which no reputable psychiatrist would defend

Dr Winnicott's greatest objection, however, appears to result from the implied threat such treatments have to his apparently beloved "analytical" psychology This is too big a subject to dilate upon here, but I would ask Dr Winnicott to consider whether he is not himself "unscientific" in assuming that the many amazing concepts of Freud (which, by the way, are outside the realm of scientific proof or disproof) are the only ones of value in the psychological approach? For example, modern child guidance, with its right insistence upon the emotional development of the early years and the importance of "security and affection," appears to derive nothing from Freudian theories but to be based upon the work of Adler (who rejected Freud's teachings) and of Cameron and others in England

Lastly, I am of the opinion that such misconceptions as are evident in Dr Winnicott's paper must to a great extent be placed at the door of psychiatrists themselves When we as individuals become less "aloof" and "mysterious," and when we cordially invite all neighbouring practitioners and specialists to visit our hospitals at any time and to see their own or other patients undergoing such treatments, we shall hear very little of the "unconscious hate" that notoriously coloured the management of the insane up to recent times—I am, etc.,

Armagh N Ireland

ROBERT THOMPSON

Allergic Reaction to Penicillin

SIR—I wish to report the following case history showing a marked allergic reaction to penicillin therapy which occurred in the maternity department of Dorking County Hospital

CASE REPORT

A primipara aged 40 was admitted as an emergency with the history of early rupture of membranes 76 hours previously, uterine inertia, and commencing foetal distress, as evidenced by passage of meconium, though heart sounds were regular and of fairly good quality Rectal examination showed the cervix half dilated, head in brim not fixed

Lower segment caesarean section was performed under general anaesthesia shortly after admission Much meconium in uterus Baby shocked but responded well

In view of the history and expected stormy convalescence penicillin therapy was instituted immediately after delivery The preparation used was penicillin in oil, given intramuscularly with a preliminary dosage of 400,000 units followed by 200,000 units 12 hourly On the second day after delivery paralytic ileus developed Treatment consisted of morphine, half-hourly duodenal aspiration through a Ryle's tube acetylcholine intravenous drip, radiant heat to abdomen, and turpentine enemata Response to treatment occurred within 48 hours On account of a sustained low grade pyrexia during the puerperium due to a mild genital tract infection, penicillin in oil in the above dosage was continued for 16 days, the total dosage being 6,400,000 units

On the day following cessation of penicillin therapy a severe urticarial reaction occurred It affected the face and limbs and later involved the trunk also It was unaccompanied by fever or tachycardia but caused such severe pruritus as to keep the patient in the next bed awake by the vigour of the scratching Adrenaline, calcium gluconate, and local sedatives gave some relief, but fresh patches kept appearing for a total duration of 6 days, and then cleared up completely Mother and baby were sent to the hospital on convalescent home and discharged well and thriving 5 weeks following delivery

I would add that this patient had not previously had any penicillin therapy—I am, etc.,

Dorking Surrey

J C CUTHBERT

"Benadryl" Treatment of Penicillin Allergy

SIR—Accounts of the allergic response to penicillin have appeared recently in the journals These reactions have been both to intramuscular and local applications of the drug The commonest reaction is urticaria alone but occasionally a full anaphylactoid response is seen with fever, hydrarthrosis, enlargement of the lymph glands and bronchial spasm This often occurs 10 to 14 days after the commencement of penicillin treatment and resembles serum sickness The intense pruritus which accompanies the urticaria is usually the most troublesome feature, causing scratching and inevitable insomnia

A patient of mine (G A), a girl aged 19 years, developed a paronychia, and I first saw her with pus under the left thumb-nail and slight lymphangitis The nail was removed, penicillin in oil, 125,000 units in 1 ml, was given daily for three days, and the thumb healed uneventfully

Ten days after the commencement of penicillin she developed an urticarial rash on the back and shoulders, this was associated with intense itching She had no family or personal history of allergy, and as far as could be ascertained she had not been exposed to any other allergen The following day, after a sleepless night, she had a temperature of 100° F (37.8° C), there was generalized urticaria, which was most marked about the face, and she was also dyspnoeic On examination the axillary and inguinal glands were enlarged, on auscultation of the chest there was a marked expiratory wheeze there was no evidence of hydrarthrosis Calcium lactate 30 gr (2 g) and phenobarbitone 1 gr (65 mg) were given six-hourly, but the following day the symptoms had increased

Having used "benadryl" (dimethyl aminoethyl benzhydryl ether hydrochloride) successfully in angioneurotic oedema, I commenced treatment with 100 mg (two capsules) at once and a further 50 mg six-hourly The response was most dramatic within an hour all urticaria had disappeared, the itching and dyspnoea ceased, and the patient was symptom free There has been no relapse

While further cases will have to be described "benadryl" appears to be the drug of choice in the long term treatment of anaphylactoid phenomena, "benadryl" being perhaps to adrenaline what trinitrin is to amyl nitrite—I am, etc.,

Liverpool

GEOFFREY DEAN

Pruritus Ani as an Allergic Condition

SIR—The association of pruritus ani with allergy is hardly investigated The unsatisfactory results of treatment in many cases, however, make it desirable to get better information on aetiological factors in these conditions A case of a man who came into my observation first on July 8 1946 illustrates this well

The patient was 66 years old There was a family history of allergy, the son suffered from asthma a daughter had attacks of urticaria The patient has had sinus and antrum operations for "sinus infections" from 1898 on, the last time in 1929 In 1943 piles were operated and "proctocaine" injected The skin proved to be allergic to skin disinfectants All these years the patient suffered from severe irritation of the anal region which "made life miserable" to him Three weeks before he saw me first he again had piles removed by operation A slight attack of pruritus had occurred 40 years earlier He has also suffered from urticaria and eczema on his head, otherwise he has been a healthy man all his life

On examination I found a scar on his right forehead due to the operation on his right frontal sinus The anal region was in an irritated state, excoriation, thickening, and oedema of the skin were marked, and there were cracks and slight fissures in the perianal region The middle lobe of the prostate gland was moderately enlarged A differential blood count showed a hyper eosinophilia of 6%, basophils, 4%, polymorphs 67%, lymphocytes 23% Skin tests gave positive results to moulds, cheese, and other food proteins His condition was worse when constipated

From his faeces *Bact coli* and *Staph aureus* were cultured and used for an autogenous vaccine together with a desensitizing mixture of the positive allergens Apart from that the patient was given vitamin E and testosterone tablets Local treatment was discontinued His condition started to improve after three weeks and the anal findings showed a normal picture and normal skin ment The patient was last re-examined on May 8 and was found absolutely well and the anal region normal As repetition

of his blood count elsewhere had given no signs of hypercosinophilia I had it re-examined in October, when a "hypercosinophil phase" of 11% was found

F R Rugeley published a paper on allergic causes of pruritus ani recently (*Annals of Allergy* 1946 4 374 and 396) and reported about 14 cases of pruritus ani in which a connexion with allergic causes was revealed and rapid improvement achieved by treatment on these lines, whereas the conventional treatment, tried before, had proved to be unsuccessful. He holds the opinion that excoriations, oedema of the skin, thickening or exudation vary in intensity and that papillitis fissures, and other changes thought to be causative factors are often secondary and not primary changes. He recommends strongly that allergic causes of pruritus ani should be investigated before radical procedures are suggested, such as surgical interference, x-ray treatment, local injections, divisions of nerves, or tattooing of the anal margins with anaesthetics—I am, etc.,

London W1

E M FRAENKEL

Congenital Hepatic-duct Malformation

SIR—Length of survival may warrant recording the following case. A female child 10 months old had been jaundiced since her normal birth. Weight records were 7 lb (3.1 kg) at birth, 9 lb (4 kg) at 6 months, 12 lb (5.4 kg) at 10 months. Absence of breast milk had resulted in cows milk feedings. Three older children were healthy.

The child was lively and profoundly jaundiced. Her spleen extended three fingerbreadths below the ribs, and the nodular liver extended below the umbilicus. The urine was dark, contained bile, and the stools were light. Her haemoglobin was 65% red blood count 3 000 000, white blood count 5 100, and the Wassermann was negative in mother and child.

On Dec 12, 1946, the abdomen was opened in the hope of finding a gall-bladder for anastomosis. A small amount of bile-stained fluid appeared. The enlarged liver was hobnailed and had rounded borders. No gall-bladder and no extra-hepatic ducts were present. The spleen surface was granular. Prof J H Fisher examined a biopsy specimen and reported obstructive biliary cirrhosis. Post operative condition was good until Dec 18, when hepatic failure developed. On Dec 23 the wound disrupted with bowel prolapse. The child was unconscious, and the wound was closed with through and through silkworm sutures without anaesthesia. The child died eight hours later having lived ten months and eight days—I am, etc.

Arkansas U.S.A.

FRANK RIGGALL

De Morgan's Spots

SIR—I was much interested to read the paper by Capt A R Murison, Lieut J W Sutherland and Flying Officer A M Williamson on De Morgan's spots (May 10, p 634). Their observations on a very large number of patients are a valuable addition to the literature on the subject and incidentally a confirmation of earlier findings by other authors. I would however like to point out that the literature on the 'ruby spots' is by no means extremely meagre and the erroneous impression that 'there is an entire absence of precise information on their significance' is obviously due to some confusion in the terminology.

'De Morgan's spots' is an obsolete term almost wholly unknown outside this country and rarely met with even in the British literature. The more or less generally accepted name for this type of telangiectatic skin lesion is angioma senile. This term is generally used in the international literature, but also by English authors (e.g. Colcott Fox, *Brit J Derm* 1908, 20, 145) and in English textbooks of dermatology (McLeod Sequeira). Less common synonyms are angioma eruptivum, angioma tuberosum, angioma nodulare cutis, senile ecstasia, perles sanguines. The pathology of angioma senile, including its relationship to malignant disease, has been the subject of comprehensive investigations mainly by French and German authors. In my monograph on Haemangiomata and Telangiectasias of the Skin (Jadassohn *J Handbuch der Haut- und Geschlechtskrankheiten* Vol 12 Pt 2, Berlin, Julius Springer, 1932) I dealt exhaustively with angioma senile (pp 379

398, 404). May I be allowed to quote just a few passages from what I said then:

'These tiny multiple angiomata are of interest also because under the name of Leser-Trélat's symptom, their presence has occasionally been regarded as indicative of internal carcinoma. Trélat de Bouciud and subsequently Leser believed that the incidence was higher in patients with internal carcinoma. The authors (not De Morgan) suggested therefore that senile angiomata had a certain diagnostic significance, especially when present in early adult life and in great number. This concept, has however, been disproved by Gebele, Raff, Reitzenstein, Rosenbaum, A Symmers, and Wolff. Summing up I said:

There is little evidence to support the view that they [i.e. senile angiomata] are of pathognomonic significance in the diagnosis of malignant tumours.

As for the histological structure of angioma senile, it seems not quite correct to say that the lesions have the character of simple haemangioma. More aptly they may be described as telangiectasias because—I am quoting again from the above monograph—'there is no evidence of a formation of new blood vessels. Development and enlargement of the minute tumours are entirely due to dilatation of (pre-existent) capillaries or small veins. In addition, pathological changes of the cutaneous tissue, such as destruction of the elastic fibres and degeneration of the collagen are often though not in all specimens found to be present in the neighbourhood of the dilated vessels—I am, etc.,

Manchester

L WERTHEIM

Prognosis of Primary Pleural Effusions

SIR,—I read with great interest Dr Brian C Thompson's article (April 12 p 487) on the prognosis of primary pleural effusions. I would like to suggest a fourth factor which seems of equal importance to the three that he describes as being necessary in the correct assessment of the development of the effusion over a period of five years. This is the nature and duration of the initial treatment of the pleural effusion. Figure quoted by Coope suggest that a period of several months treatment under sanatorium regime when the pleural effusion is first manifested greatly reduces the incidence of tuberculosis subsequently. He states that in cases thus treated there is less than a 10% incidence of tuberculosis, whereas in untreated cases figures up to 60% are quoted.

It would be very interesting to learn whether Dr Thompson's cases underwent any sanatorium treatment when the pleural effusion first developed, and, if so, how this group compared with those who had no initial treatment with regard to the development of tuberculosis subsequently—I am, etc.

Acute Non-specific Diarrhoea and Dysentery

SIR—I was surprised to read Dr G R Kershaw's article (May 24, p 717) because I had not heard such views expressed by anyone of the present generation. I can only say that some of us slept for two months in a troopship to the Far East without at most a pair of short pants for cover, with a louver directed at our naked forms without ill effect. In India many of my acquaintance slept almost nude under fans through very hot weather and they reputedly were less frequently troubled with epidemic diarrhoea than others who slept in a more temperate way.

Any epidemics of local "tummy rot" could well be ascribed to the lack of hygiene in Indian cooks and cookhouses. In fact one was persuaded that the less covering to which one could accustom one's body the more resistance one achieved to local minor diseases—a view which received the approval of Army authorities—I am, etc.

Bournemouth

G DALLEY

SIR—I read Dr G R Kershaw's article on acute non-specific diarrhoea (May 24 p 717) with interest. From my own experience I am convinced that chilling of the abdomen is a common cause not only of acute diarrhoea but of chronic locomotions. During six years in South China I was able to state the effects of chilling on the abdomen, often after violent

exertion such as digging or mowing a rough lawn with an old lawn mower. The abdominal wall felt icy to the touch, and after such exertion I would have an acute attack as described. It could not be put down to icy water as we had no refrigerator and usually the water remained tepid after boiling. Stools were negative.

Apart from these acute attacks I normally had three or four loose stools daily during the hot weather. I eventually found that a 'belly pad' consisting of about a square foot of woollen vest, lined on the inside with an old piece of 'lock-knit' cotton material, tied round the neck and waist, was almost specific. The Chinese (Hakka) people dress their small children in a 'belly pad' in the hot weather—I am, etc.

ALAN A. CROOK

Acid Drinks and Sulphonamide Therapy

SIR—Dr Petronella Potter (May 10, p. 654) raises a theoretical point on the effect of fruit-juice drinks on the urinary pH, but I don't think she can have taken the precaution of testing it in practice. The same point occurred to me when working with heavy doses of sulphadiazine in a country whose climate required a large fluid intake to maintain adequate urinary output. The intake was largely of fresh orange- and lemon-juice drinks. To test their effect on urinary pH, plain water was substituted for them in one group of patients. There was no significant difference in the urinary pH of the two groups as tested by universal indicator. There therefore seemed no practical justification for withholding the fruit drinks—a welcome conclusion, since the patients' general condition suffered on the water regime, which they did not enjoy taking and would avoid if possible.

As citric and tartaric acids and their salts are organic and liable to catabolism in the body, even Dr Potter's theoretical arguments are in doubt—I am, etc.

Oxford

C. W. M. WHITTY

Post-operative Pulmonary Atelectasis

SIR—Dr M. H. Armstrong Davison (May 17, p. 695) says that I am tilting at illusory windmills in emphasizing the importance of the routine use of simple postural coughing in the avoidance and treatment of post-operative atelectasis. I was not trying to instruct Dr Davison himself, I think that would indeed be tilting at an illusory windmill because clearly we are in general agreement, but I am certain that we can all do a most important service by emphasizing the principles of simple prophylaxis and treatment which are not yet sufficiently known.

Bronchoscopic aspiration has many advantages in proper circumstances. The object of my letter was to protest against the fostering of the belief that when confronted with a post-operative atelectasis one should at once perform or ask for a bronchoscopy. It is true that anaesthetists should be able to perform bronchoscopic aspiration, but it is going to be a long time before there are enough anaesthetists up and down the country skilled enough to do so. In the meantime post-operative sputum retention is a very common occurrence in all hospitals, great and small. Its ill-effects can be avoided or overcome in the majority of cases by a simple drill available at once in every one. I find that there is very widespread ignorance of this fact and I think that all teachers have a duty to emphasize to house officers and nurses that an efficient remedy lies in their own powers and should be used. Bronchoscopic aspiration should be reserved for the small proportion of cases that fail to respond at once—I am, etc.,

London W 1

R. C. BROCK

Use of Drugs in Asphyxia

SIR—For the correct use of drugs in asphyxia it is at least desirable to know something of the physiology of respiration. Prof Barcroft's recent researches into foetal respiration have shown us a whole new mechanism of respiration which is hardly hinted at in the normal physiology textbooks. They serve to emphasize the essentially reflex nature of respiration. So far as the brain is concerned normal ordered respiration involves a number of centres at various levels in and above the medulla—asphyxia "blackouts" (in flying, etc)—these centre from above downwards, and in cases where the onset of respiration

is postponed the possibilities lie in the establishment of a reflex gasp involving some cutaneous or other peripheral stimuli acting at the lowest level—i.e., low down in the medulla. When once respiration is properly established and the brain fully oxygenated, the respiration is thenceforward regulated by the well known mechanism described by physiologists. Incidentally Prof Barcroft shows that in the foetal sheep the earliest respiratory movements are elicited by touching the snout area alone, and this is, of course, the area on which the lamb normally drops when it is born, thus providing the maximum cutaneous stimulus to the most sensitive area.

In view of Barcroft's researches, the most effective way to combat asphyxia neonatorum would seem to be to apply a cutaneous stimulus—as in the traditional slapping or by directing a vigorous jet of oxygen on to the nose or into the mouth—or, if that failed, to give some drug which would enhance the sensitiveness of the nervous system so that it will respond to stimuli to which it otherwise would not—in other words, to give something in the nature of a convulsant. This justifies the old-fashioned recommendation of giving as much as 1/400 gr (0.16 mg) of strychnine (now, I think, never used though I refer to this again later) and the more modern use which I have described several times, of cardiazol-ephedrine. Cardiazol is a well known convulsant, and in cases in *extremis* I have used it successfully in doses which, in a fully oxygenated baby, are certainly convulsant. (The largest dose I have used, and with complete success, was for a baby who failed to make any response for 15 minutes but finally did so after receiving 0.5 ml intramuscularly and then two doses of 0.5 ml intracardially.)

This theoretical discussion, with its slight experimental demonstration, clears the way for a consideration of the possible bearing of Barcroft's work on the drug treatment of asphyxia in later life. We all know that asphyxia or high dosage of carbon dioxide depresses the sensitivity of the respiratory centre in the medulla, so that finally respiration ceases whatever the concentration of carbon dioxide may become. The question then becomes: Does the original basal or protopathic mechanism of respiration—i.e. responding to cutaneous stimuli instead of to asphyxia—still persist, or is it also abolished with the more normal pattern? I have already mentioned that Barcroft found that at a late stage in foetal life the cutaneous response persists in the foetus when the oxygen tension in the cerebral circulation is almost inconceivably low—i.e. when the response to asphyxia is practically abolished. There are various clinical observations which suggest that in adult life an early developed mechanism may be capable of functioning even though the normal later one is not—e.g., in insensibility due to cerebral haemorrhage, etc. the involuntary basal functioning of certain organs (bladder, etc.) shows itself even though it may have been suppressed in man for more than half a century while in some types of heart disease the ventricle may reassume its own fundamental rhythm even though for 70 years or more it has followed quite a different one impressed by the auricle. If this is so, the logical way to treat a case of asphyxia would be to try to utilize the original but dormant cutaneous method of stimulation until the re-oxygenated brain reasserted its normal method of control.

I have described in the *BMJ* and repeated at the A.M.C. the case of a boy who was immersed in the river for about 15 minutes and who was responding hardly, if at all, to efficient artificial respiration. I injected 10 ml of cardiazol-ephedrine and 1/30 gr (2.1 mg) strychnine sulphate turned him over and gave him a few vigorous slaps, with the result that within a minute he was crying lustily and continued to do so for an hour or so. He finally made a complete recovery in spite of a rising pneumonia. This is only one case, but it does suggest that the injection of convulsants in cases of asphyxia may prove a most valuable and rapid method of treatment. I stress the importance of rapidity, for though cases have recovered after prolonged artificial respiration, all the evidence we have shows that the brain is extremely liable to damage from complete lack of oxygen, and if we can reduce the period of asphyxia we can—if it is not tautology to say so—hope for a much greater percentage of complete recoveries.

It is worth mentioning in this connexion that our fathers constantly used injections of strychnine as a respiratory stimulant but this practice has fallen into desuetude since the physiologists proved that in the laboratory strychnine has no such

stimulating effect. Barcroft's work suggests that it may well be of the greatest value where the normal mechanism is failing and the organism possibly having to rely on a more primitive one. If this is so it is but one more example of the clinical acumen of our forefathers which has been discredited not because it was wrong but because its mode of action was misunderstood, or because the conditions of the physiological experiment were such as to prevent its giving a correct answer. "The proper study of mankind is man," and though cats and dogs are useful, they can never replace the acid test of human experiment. I suggest that those with the requisite opportunities might try the application of Barcroft's work in the way I have indicated—I am, etc.

Winsford, Cheshire.

W. N. LEAK.

Artificial Insemination

SIR—Dr Eustace Chessers letter (May 24, p. 738) is a valuable contribution towards a correct assessment of the problem of heterogeneous insemination. He admits having dealt with cases of homologous and heterogeneous insemination and now condemns the latter.

Recently in Newcastle we were addressed on the legal problems of this matter, which was dealt with from every aspect. We were informed that the donor should be a married man with one or two children and of proved health. I made, *inter alia*, the following remarks: "Artificial insemination of cattle is justifiable as it involves no ethical problem. The majority of the males are castrated and it is only reasonable for commercial purposes that the remainder may distribute their favours, as after all we eat the progeny. I have never done homologous insemination but I would consider it ethically correct to aid fertilization if, for example, coitus was impossible owing to vaginismus or some other abnormality. Heterogeneous insemination brings in a special factor which revolts one. What type of individual can the donor be who hawks his seminal fluid round the countryside at so much per c.c.?"

Judging by the way a large mixed audience received my remarks from personal talks, letters, and phone messages, I am sure that the bulk of them felt as I did. Dr Chessers' letter strikes me as being written by one with deep conviction—I am, etc.

Newcastle-upon-Tyne.

FARQUHAR MURRAY.

Infant Deaths

SIR—With reference to Dr S. Waddy's letter on infant deaths (May 24, p. 737), in which he draws attention to the danger of too great a weight of blankets on an infant's cot, a recent necropsy which I performed may be of interest.

A healthy baby aged four weeks was found "panting for breath" one morning in its cot and died before the arrival of a doctor. A necropsy revealed all the signs of asphyxia in an otherwise normal infant. At the subsequent inquest the mother was asked about the clothing and bedclothes of the child. The disclosure that on the warmest night of this year the unfortunate babe was bedecked in (1) a woollen vest, (2) a woollen coat, (3) a woollen night-dress and (4) woollen bootees and had as covering four woollen blankets and an eiderdown—the blankets being well tucked in—left no doubt as to the cause of the asphyxia. Comment is unnecessary—I am, etc.

Northampton.

RUBY O. STERN.

Keeping Mother and Baby Together

SIR—We have read with much interest and pleasure the paper by Prof. J. C. Spence on 'The Care of Children in Hospital' (Jan. 25, p. 125) and note that he approves of the method we have been using as much as possible for the last 20 years and exclusively for the past 6 years in a small special hospital—namely, encouraging every mother to nurse her own baby (*vide BMJ*, Feb. 3, 1945, p. 159 and Sept. 7, 1946, p. 337). Given the right conditions the system works well and gives excellent results. Babies want constant attention and 'mothering' to break the bond between mother and baby in order to introduce an unnecessary hurdle into treatment which may spell the difference between success and failure. We have noted also the objections of Drs W. E. Crosbie and J. Lorber (Feb. 15, p. 266) to the mother-and-baby system of nursing.

We in our work are of course frequently up against the same trouble of a mother finding it difficult to leave her home and family. But here is where grandma or auntie will nearly always step into the breach, someone can invariably be found to look after the home. The only insuperable difficulty is when the mother herself is ill and possibly in hospital. In such a case we get a 'foster mother,' if possible again an aunt or grandmother or other relative, and it is astonishing how soon the foster mother and baby get fond of each other and it is this bond of fondness which is so valuable to the baby patient, in its time of trial.

Again we would emphasize it is of no use putting a mother with her baby in a ward. They must have a little room to themselves which is their own private room and under these conditions the classical description by Prof. Spence of a children's ward commencing 'The room is vast—is never applicable. The simple fact is that there are not enough nurses and not enough time for baby patients to be given all the attention they require—We are, etc.

H. P. PICKERILL,
CECILY PICKERILL.

Wellington, N.Z.

Health of Children Attending Day Nurseries

SIR—The observations made by Dr Margaret E. McLoughlin as stated in her preamble (May 3, p. 591) cannot lead to definite conclusions, owing to the impossibility of assessing the relative effects of economic and environmental factors on such a survey unless the obvious course is taken of studying these vital social factors simultaneously with the purely pathological ones attempted. Out of many points which require further investigation that reading "The inference that there were no significant physical differences at the start of nursery life between day nursery children and those living at home may reasonably be assumed to apply also to the present survey" requires more evidence than that afforded by examinations by a variety of observers on 290 children "scattered all over the country" and then statistically compared to the 4,297 children in the major groups studied.

From my experience of the basis of admission to day nurseries priority is invariably reserved for mothers forced to work, the reasons leading to this necessity operate before and after pregnancy, therefore their level of nutrition and take-up of extra rations and vitamin supplements (owing to lack of free time and financial stringency) is lower than that of the normal home living mother. One would not expect the babies born to this group to have the optimum physique and resistance obtainable. Day nursery care would have to overcome this initial inferiority before any reasonable comparison could be made between them and other groups. If the statement I refer to can be scientifically proved I suggest the whole of our nutrition policy for expectant mothers must be based on a fallacy.

This report emphasizes the vital importance of good staffing and management and should reinforce the struggle to raise the standard of training in child welfare to a national university level as advocated by the report issued in 1946 by the National Society of Children's Nurseries. These "extensions of the home" must and can be made safe in order that they may assist the solution of a multitude of acute social problems—to quote a few the work of the Marriage Guidance Council—to enable the mother to meet the psychological needs of toddler, school child, and adolescent with the obvious bearing on the problems of juvenile delinquency, promiscuity, and venereal disease and to enable the mother to obtain the maximum benefit from the provision of the National Health Service for treatment for herself and young family. For all of these I welcome the suggestion that the attendance of children 'for two or three half days a week is a question worthy of investigation'—I am, etc.

Farnham, Surrey.

NORA M. JOHNS.

Food Poisoning

SIR—I was much interested to read the paper in your number of April 5 (p. 442) about an epidemic of food poisoning traced to staphylococcal contamination of sandwiches. It recalled to me a case that was clinically typical Asiatic cholera that occurred in a country practice in the Orange Free State in the year 1922. I published it in the (since defunct) *South African*

Medical Record 1922, 20 209 and asked if any similar cases had been observed in other places, there being an epidemic of "paracholera" reported about that time. Nobody took any notice of my short paper and I was disappointed not to hear of any similar cases.

As I said, the case was typically Asiatic cholera, with very violent vomiting, diarrhoea, cramps, and collapse, with rice-water stools but bacteriologically no organism was found but pure streptococcus. I wonder if such symptoms have often been associated with pure streptococcal infection. It is very interesting to note the great difference from the clinical manifestations of staphylococcal infection as reported in the paper recently published—I am, etc.,

Durban

C LUNDIE

Undernutrition

SIR—The letter from Dr Martin Herford (May 17, p 696) is extremely valuable and demonstrates the real existence of subclinical undernutrition, which is not by any means fully appreciated.

For years before this latest of wars I fed my stomach as both it and I thought satisfactorily and we both thrived. Then came the war—meals now only three courses! We—my stomach and I—assimilated these new conditions protestingly and gradually and now after all these years we have adjusted ourselves. But has my body benefited or worsened under the difference? Do I suffer from lack of calories and vitamins, or am I benefited from a compulsory deprivation of a surplus of purins and fats? Shades of Nat Gubbins dialling "Tum"! I only know that I get more indigestion than I used to do and that I tire more easily. Therefore I believe that my diet as a hard working man is inadequate and that the old scale of large and more varied meals suited me best though I doubt if Tum would now digest them—such is habit and the adaptation of the human body. Saliva flows at the thought of a pre-war meal but does carcinoma lurk in the background?—I am, etc.

DESMOND MACMANUS

Planning for Health

SIR—I ask for space for a matter of importance in the world of positive health and to air a flouted first principle in the pursuit of planning. In 1932 I selected a camping ground for boys at Snettisham Beach, Norfolk. It had much to recommend it. It was far from houses, yet within a mile of a station, it had a good water supply, was within the 'dry belt' was the nearest seaside place to some of the East Midland towns, the bathing and sailing were fairly safe, and at low tide there were miles of sands, a gloriously healthy arena for games, cockling, and other noble sports. For seven years many hundreds of boys from all over the country enjoyed free camping there and during the war half the camp, about nine acres, was taken over by some 800 Americans.

After the war the camp was handed over to the Workers' Travel Association, a non-profit-making concern with an excellent record which provides holidays for workers. With increasing holidays with pay this body has an extra job of work to do and it was thought that they would utilize this camp to the best advantage. When however, they applied to the local planning committee for permission to raise the necessary buildings, our modest ones having been levelled by the Allies, they met with a refusal.

The grounds for my committee's decision are to prevent danger or injury to health arising and further detriment to the neighbourhood in view of the low lying nature of the land which is liable to flood.

If this ill conditioned sentence means anything it means that the land is liable to flood and that the sewage from the camp might spread round and infect the neighbours. But there are none and in any case the slope of drainage from the camp is down to marsh land where there is no house for miles. Moreover the camp land has never been flooded within living memory nor could it be unless eight miles of marsh land lying 20 feet below were flooded first. That sentence was written in January of this year then came the floods over much of the country and county but this land was not flooded nor was the marsh land below.

In these circumstances I wrote and asked the local planning committee the names of their health experts, these men who were so demonstrably wrong and who in my view used the excuse of health to prevent workers gaining health. The reply was "I am not at the present time, in a position to supply you with the information you request or to offer a further opinion on the matter."

Now this may be a local affair, but I suggest that a principle of first importance is involved. Planners and experts must not be anonymous, otherwise we have no guarantee of their ability or that they are not stupid or self interested or both—I am etc.,

Rye, Sussex

C G LEAROLD

Entry to Dartmouth

SIR—I had hoped that someone more learned than I would have raised this matter of the change of the age of entrance to Dartmouth from 13½ to 16. I have had considerable experience of schoolboys of all ages and classes. It seems physiologically unsound to transfer a boy to the strict discipline of the R N C in the middle of adolescence. The present method whereby a boy enters the Navy at the onset of adolescence or at the end, or at least when it is stabilized, is sound, and the results are admittedly good very good. At present a number of boys are taken from elementary schools at the lower age with, I understand, satisfactory results. It is hard to see what advantage is to be gained by removing a boy at this most unstable period into a strange milieu—I am, etc.,

Clifton Bristol

R G COOKSON

Tobacco

SIR—In your recent leading article (April 26 p 570) on this burning (!) topic you twice referred to tobacco smoking as a habit. This is a common but in my view a serious error. Tobacco smoking is not a habit but a drug addiction, a disease. Untruthfulness is an outstanding symptom of the drug addictions. It is well recognized in morphinism and cocaineism but it is not generally realized that, on matters concerning tobacco, tobacco smokers are exceedingly untruthful. The untruth that smoking is a habit is perhaps the most important. Other fundamental untruths circulated by smokers are that smoking is a vice and tobacco a luxury, and I would be grateful if you would allow me space in which to 'nail' them.

The essence of a habit is that it is acquired by repetition and references to tobacco smoking as a habit carry the implication that the repetitive act of administering tobacco smoke—puffing—is the essence of tobacco smoking, not intoxication with nicotine, carbon monoxide, and pyridine bases—the main constituents of tobacco smoke. Even in bringing about the administration of tobacco smoke habit is much less important than craving for tobacco, as anyone cured of tobacco addiction knows. Is opium smoking also a habit and intoxication with the alkaloids of opium of secondary importance? Clearly the essence of tobacco smoking is the tobacco and not the smoking. Satisfaction can be obtained from chewing it, from snuff taking, and from the administration of nicotine. The majority of diseases are intoxications of one kind or another and the intermittent intoxication induced by tobacco smoking must surely be accounted a disease. The terms "drug habit" and "smoking habit" ought also, in my view, to be forsworn.

The untruth that smoking is a vice is somewhat nearer the truth. Vice or moral deterioration is an essential symptom of drug addiction. It is merely however a symptom (secondary to craving) the disease is drug addiction. It is revealed in the case of tobacco smoking in frequent non observance and sometimes obliteration of non-smoking notices in abuse of those who ask that these be observed in untruthfulness about tobacco, and in the frequent failure of smokers to honour their obligations. An example of this much to the point is the failure of our tobacco addicted profession to prevent this serious disease which is no more difficult to prevent than addiction to opium. Tobacco is treated in this country not as a toxic drug of addiction which it is but as a luxury which it is not. It is not included under the provisions of the Dangerous Drugs Act, it is sold to the public in almost unlimited quantities, and its

high taxation leaves no room for any doubt about the Government's view, a view for which we must accept the main responsibility. To the craving addict his drug seems a luxury, to individuals who do not crave it has no value, unless it be a medicinal value when given to non-addicts.

Innumerable variations of these and of other untruths about tobacco circulate freely but the truth about tobacco is generally taboo. Even this last budget has failed to raise this powerful drug taboo to any important extent. Untruths about tobacco proceed from smokers' delusions. The delusions of tobacco smokers are systematized, and localized to matters concerning their drug. Outside their delusional system smokers are perfectly rational. Their delusions are, however fixed by craving for tobacco and undeception is therefore exceedingly difficult.

Drug addiction, according to Glover, 'borders on a line between psychoneurosis and psychosis'.³ It seems to me, however, that it is a form of toxic psychosis. What better evidence of national insanity than the spending of one-third of our American loan on bringing into this country hundreds of tons of toxic and therapeutically useless drug?—I am, etc

NHS Act and Split Services

SIR—Recent views of experienced tuberculosis officers of a large county and borough—Dr G Lissant Cox and Dr H Vallow (April 26, p 577, and May 17, p 693)—confirm objectionable features of split services and dual control, which I, too, drew attention to, not only on tuberculosis but also in relation to mental health, maternity and child welfare and sick visiting. Such control will not only affect officials but also existing multifarious committees.

"Tuberculosis-care Work," published (*Tubercle* 1920, 1, 317) as a then tuberculosis officer, largely helped to model in Leeds a committee for the care and employment of tuberculous subjects (later largely financed by the city council), without it no tuberculosis scheme can be adequately controlled. Since 1930, as the only medical member of the Leeds city council and chairman or deputy of its mental health committee dealing with defectives, one is aware of the usefulness of the Mental Care Committee for home supervision and training of defectives. Our experience in Leeds of a separate mental health committee has proved that the defective problem has been more efficiently controlled than it would have been by a subcommittee of a health committee or of a large joint board. Again, as a former chairman of a maternity and child welfare health subcommittee I appreciate the activities of local welfare centres and nurseries for the efficiency of that service.

The central and regional administrative structure is undoubtedly a compromise to placate the conflicting interests of local authorities, voluntary hospitals, and the profession. Unless existing local machinery is more utilized and unified, day-to-day management will be ineffective. It will be almost impossible for the proposed small set up to cope with routine work of vast areas and added population.

The West Riding Mental Hospital Board (of which I have long been a lone medical member) administers lunacy for the county and for five large and five small boroughs with 54 elected members and four large hospitals. We have eight large and twenty routine committees two or three half-days fortnightly and manned by half the board for the month. Patients look up to their local representatives with requests on visiting and discharging days, also municipal hospitals, tuberculosis maternity work and other institutions take several half days for established routine. I am sure it will be impossible for many medical members to spare this time.

Active participation by the profession on policy, planning and regional staffing is undoubtedly necessary. But for local management and routine the Minister may be well advised by regulations to continue to use existing machinery of large authorities whose usefulness has been proved by including a quota of the regional members and their executive staff—I am, etc

Leeds.

Z P FERNANDEZ

POINTS FROM LETTERS

Volvulus of Small Intestine in Hernia Sac

Dr W E HADDEN (Bansang Hospital, The Gambia) writes. M M, an African male of 35 years, was admitted to Bansang Hospital with the diagnosis of strangulated right inguinal hernia. Herniotomy had been performed here three years previously on the left side. The patient stated that the right hernia had appeared very soon after the operation on the left side. The day before admission he had felt pain in the right hernia at 2 p.m. while cutting grass with a bill hook, and had gone home. Next morning the pain became worse and he appeared at hospital at 12.30 p.m. He had not vomited. On examination, temperature, pulse, and respiration were normal. There was a painful swelling of the right scrotum about the size of a grapefruit. Reduction was not attempted. Operation was performed at 2 p.m. the same day, the anesthetic being 2 ml heavy nupercaine intrathecally. On opening the hernia sac a loop of plum coloured small intestine presented and on being brought out of the wound was seen to be strangulated by rotation of the loop on its mesentery. This loop of bowel was viable. Further exploration of the sac showed two normal loops of small intestine to be also in the sac with a small quantity of fluid. The loops of intestine were returned to the abdomen and the sac excised after ligating its neck. Repair was performed and the sac closed. The patient was discharged after twenty-one days, the only complication being a stitch abscess. This case is interesting in that volvulus occurred in a hernia sac and that two other loops of bowel in the sac were normal. No cause could be found for the volvulus, unless the rhythmical semi rotary motion of cutting grass with a long knife all day had initiated it. I am indebted to Dr C W F Mackay, Senior Medical Officer The Gambia, for permission to publish this case.

The Nursing Crisis

Dr G C PETHER (Colchester) writes. Is it not possible that one factor influencing the desire to escape from hospital is this. Some years ago I had the opportunity to observe the change in atmosphere when a municipal hospital was taken over by a county authority. Now under the old employers the nurses and doctors met the municipal representatives on many occasions, social and otherwise. It was not difficult to feel loyalty and affection for an organization of limited size and which had local roots. Pay and conditions were fairly good. When the county authority took over they tended to improve, but so many of the intangibles were lost. The personal touch disappeared. It was more difficult to feel either loyalty or affection for an enormous organization, and this organization was not distinguished for its good manners in handling its staff. These things happened in a large city—one of the loneliest places in the world, as we all know. Many a time a young nurse would weep from sheer loneliness and sry, 'I've been here five years and I haven't been in anyone's house once'. No doubt there were many pious and kindly people near by who were engaged in supporting missions to the heathen in foreign parts. The strain of this kind of institution life could nevertheless be tolerated if members of the staff felt a happy family with their local loyalties and affections. If you take these away and make a nurse No XYZ 54879 of the Southern Hospital Regional Authority, how can she continue to give such devoted service? Are not our planners planning away all our personality and all our affections? Surely these matters have something to do with our present discontents.

Strange Encounter

Dr J SULLIVAN (Manor Park, Essex) writes. In the early hours of the morning I was recently called to an emergency maternity case in a 'pre fab'. On opening the door a pallid woman swayed forward into my arms (reminding me of one of those American films in which someone opens a cupboard door and a corpse falls forward). I tried to get her back to bed and on the way to the bedroom I became aware of another woman crouched behind her, dogging her footsteps and holding a newspaper parcel in her arms. In the bedroom I saw a loop of umbilical cord hanging from the parcel and realized that it contained the newborn baby. A panic stricken and completely helpless husband hovered in the background. On inquiry I found that the woman had delivered herself of the baby into the lavatory basin. The mother (a primipara) and the baby are doing well. No midwife was available at the time.

The Pemmican Journal

Mr H A BRUCE FRCS (Toronto) writes. I appreciate very much your kindness in sending me the abbreviated copy of your *Journal* published on Feb 22 of this year, which will be of great historic interest. When I have finished with it I will pass it over to the Academy of Medicine in Toronto for their records. I wish to commend you for your enterprise in not failing your subscribers when you are faced with a shut-down by the Government.

Obituary

Dr CLAUD FRANCIS DRUITT, of Walton-by-Clevedon, Somerset, died suddenly at his home on April 11 at the age of 77. Dr Druitt was a student at the Royal Hospital and University College Bristol, where he qualified in 1896. He was assistant house physician and later casualty officer at the Bristol General Hospital before settling in general practice in Derby. After he had been in practice there for thirty years he retired and went to live in Somerset. He had been on the town council at Derby for several years and was a lay reader at St Mary's Church, Boulton.

F G B writes. He was much loved at Clevedon. He was vicar's warden at Christ Church, where he will be sadly missed. He was deeply interested in home and foreign missions and was ever ready to lend a hand in helping them. A great lover of nature, he was an accomplished ornithologist, and during his lifetime made a large collection of British birds and insects, which he presented to Halesowen Grammar School. He gave talks on nature subjects to children at schools and started a nature club for boys. Claud Druitt was a great Christian and he left a deep impression on those who knew and loved him.

Dr JOHN MCGREGOR HARTLEY REID died suddenly on April 30 at the age of 55. John McGregor Reid graduated M.B., Ch.B. from Aberdeen University in 1914, and took the D.P.H. a year later. In France in 1915 at Ypres he suffered in the surprise gas attack. After recovery in England, he returned to France until 1918, and then served in Egypt and Palestine until 1920. On being released from the R.A.M.C. he held various resident appointments at the Leicester Royal Infirmary. Subsequently he was house surgeon to Sir Robert Jones at the Royal Southern Hospital, Liverpool, and then assistant medical officer in the Aberdeen asylum. His mother lived in Italy, and two sisters in France, and frequent visits to these countries and a period of study in Paris with his natural facility for languages, made him fluent in both French and Italian. In 1925 he settled in the West End, where he built up a large practice, especially in connexion with clubs, hotels and the stage. Not long afterwards he became a medical officer to the Shaftesbury Homes and Arethusa Training Ship, and began to interest himself in dermatology. He was attached to St John's Hospital for Skin Diseases for fifteen years, latterly as the senior registrar. Every member of the visiting staff knew him well, and there were frequent calls upon him to act as deputy. He had charge of the varicose vein clinic, and its organization was entirely his own. During the recent war he was in residence in London. Mrs Reid remaining with him throughout. They suffered heavily from bombing without receiving actual physical injury. Windows were repaired several times and their furniture was all lost, but they remained to hold together the skeleton practice of those times and to keep on with the work at St John's Hospital. Unfortunately those raids told on Reid's health affecting the chronic bronchitis from which he had suffered since he was gassed in France. His health began to decline. In spite of this he responded with tenacity to every call made upon him by patients and hospital doing a full day's work almost to the time of his death. He was a man of character whose loss will be felt by many and a heartfelt sympathy is extended by all to Mrs McGregor Reid.—H C.

Dr GEORGE SMITH BANKS, formerly regional tuberculosis medical officer for the City of Aberdeen and the counties of Aberdeen and Kincardine, died at his home at Musselburgh on May 9 at the age of 67. The son of a school master in Dumfriesshire he graduated at Edinburgh University in 1905 and after holding various house appointments obtained the D.P.H. in 1909. Soon afterwards he was appointed resident physician and assistant medical officer of health at the City Hospital, Aberdeen. In 1911 the tuberculosis scheme began to take shape under the then M.O.H. the late Prof M. Hay. Dr Banks with the late Dr Arthur Hugh Lister, started the tuberculosis dispensary in Aberdeen and the first wards devoted entirely to the treatment of tuberculosis were opened. In 1912 he became tuberculosis officer and when the regional public health services were initiated in 1928 he became the chief regional officer. He rapidly developed an extensive tuberculosis service and except for a short interruption during the 1914-18 war was continuously engaged in his specialty. Eventually in the city alone he had some 220 beds available for his patients. In 1919 he was appointed lecturer in tuberculosis at Aberdeen University. He had been a member of the British Medical Association throughout his whole professional

life and an active member of the Tuberculosis Society of Scotland. It would be difficult indeed for those who have not worked daily with Dr Banks to realize his enormous capacity for work, his clinical acumen, and his loyalty to the public health department which he so ably served for thirty-five years. He is survived by his wife, a married daughter, and a young son.

Dr SAMUEL ALLAN SHIACH died at the age of 77 at Ardgilzean, near Elgin, on May 2. After graduating M.B., C.M. at Edinburgh in 1891, he took his M.D. in 1893 with distinction. His first appointment was as senior house-surgeon at Bradford Infirmary, and there followed some three years as pathologist and assistant medical officer at the county asylum, Lancaster. He then entered general practice in Llanishen, near Cardiff, in 1898. For thirty years Dr Shiach carried on an extensive practice. Many have cause to remember his shrewd guidance and willing advice in all manner of problems. His sound character and blunt kindness instilled confidence in all those who sought his aid. For many years he was an enthusiastic supporter of the Cardiff Medical Society, of which he was an ex-president. Indifferent health led him to retire from practice in 1928 and he settled in Guildford, where he soon made many friends and continued to take an active interest in medical and worldly affairs. During the war Dr Shiach returned to his native Scotland, where after some five years of failing health, he died, leaving a widow and one son.

Dr CHARLES PERCY WOODSTOCK died suddenly on May 18 at his home in Bournemouth. He had been in failing health for some time yet kept at work for as long as his physical strength allowed. A student at Anderson College and the University of Glasgow, he qualified in 1899, afterwards occupying various house appointments, then sailing East on several voyages as a ship surgeon before settling in general practice in Bournemouth. Except for the period of the 1914-18 war, during which he was on military service, he continued to practise for forty years. For thirty-five of these he was honorary medical officer to the Firs Home for patients with advanced tuberculosis.

S W S writes. Woodstock's love for the sea persisted all his days showing itself in the invariable nautical blue suit with reefer jacket he wore while doing his practice. He was a bachelor and for years he had been a 'living landmark' about the Talbot Woods district of Bournemouth. He was held in great esteem by his colleagues and by a host of patients and friends, by whom he will be much missed.

Universities and Colleges

UNIVERSITY OF LONDON

The title of Professor Emeritus of Obstetric Medicine in the University has been conferred on Francis James Browne, M.D., Aberd. F.R.C.S.Ed., F.R.C.O.G., on his retirement from the University Professorship of Obstetric Medicine at University College Hospital Medical School.

Alan Kekwick, M.B., F.R.C.P., has been appointed to the University Chair of Medicine tenable at Middlesex Hospital Medical School as from Oct. 1, 1946.

E. S. Horning, D.Sc., has been appointed to the University Readership in Experimental Pathology tenable at the Royal Cancer Hospital from May 1.

UNIVERSITY OF LEEDS

On July 16 the honorary degree of Ph.D. will be conferred upon Henry Alvin Mahony, L.D.S., Principal Dental Officer, Ministry of Health, and William Goodwin Senior, L.D.S., Dental Secretary of the British Dental Association, on the occasion of the annual congress of the British Dental Students Association at Leeds.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

P. C. P. Cloake, M.D., F.R.C.P., will deliver the Humphry Davy Rolleston Lectures at the College, Pill Mall East, S.W., on Tuesday, July 15, and Thursday, July 17, at 5 p.m. His subject is 'The Treatment of Disseminated Sclerosis by Artificial Pyrexia and Prolonged Administration of Arsenic'.

SOCIETY OF APOTHECARIES OF LONDON

On Tuesday, June 17, the Society is to confer its Gold Medal, in triplicate, upon F. H. S. Curd, D. G. Davey, and F. L. Rose in recognition of their joint research which culminated in the discovery of piludrine. The ceremony is called at 8 for 8.30 p.m. and will be followed by a soirée.

Medico-Legal

WILFUL REFUSAL OF INTERCOURSE

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

Since the passage of Herbert's Act in 1937 wilful refusal of sexual intercourse from the beginning of the marriage has been a ground for a decree of nullity, but once the marriage has been consummated the remedy of nullity is not available and wilful refusal is not in itself a ground for divorce. A recent decision of the House of Lords¹ has defeated a husband's plea that it should be treated in law as a form of desertion which is a ground for divorce if it continues for three years. A sergeant in the Royal Air Force aged 22, married during the war a spinster of 30 and lived in the wife's two-roomed flat when he was on leave. Sexual intercourse took place for the first four or five months, but when the husband next came on leave the wife said that she had prepared a separate bed for him and did not wish to resume marital relations, because she thought sex was beastly and did not want any more of it. In other respects they lived together as man and wife, taking their meals together and going out to clubs and entertainments. In spite of the husband's repeated requests the wife would never again allow intercourse.

Desertion has never been defined either by statute or by a judge, and Lord Jowett, Lord Chancellor, declared that he would follow this example. In 1924 Sir Henry Duke (afterwards Lord Merivale) laid down that refusal of sexual intercourse was not desertion, and this ruling was followed many times before Herbert's Act in 1937 made desertion a ground for divorce. The Lord Chancellor did not think that Parliament, in passing Herbert's Act, could have intended the word "desertion" to bear a meaning which it did not naturally bear and which judicial authority had so recently denied to it. He disagreed roundly with Lord Justice Scott's dissenting judgment, given when the Court of Appeal by a majority decided against the husband. The Lord Justice had reasoned that marriage, wherever it took place, was to be regarded as Christian marriage, the Prayer Book stated that one of the objects of marriage was the procreation of children, sexual intercourse for the procreation of children was fundamental to the marriage state, therefore the wife who refused sexual intercourse deserted her husband. This dangerous and fallacious argument, said the Lord Chancellor, proceeded on the basis that any fundamental breach of the obligations of holy matrimony as laid down in the Prayer Book constituted desertion under Herbert's Act. It would apply to a marriage duly consummated in which one spouse was unable through physical infirmity to procreate children. The law of the land could not be coextensive with the law of morals, the civil consequences of marriage could not be identical with its religious consequences. Marriage meant different things to different persons according to their upbringing, outlook, and religious belief but must have the same legal consequences for all. The solution to the present question must be found not in a consideration of the Christian doctrine of marriage but in a true construction of the relevant Acts of Parliament. Further, it was most undesirable for a court to inquire into the secret intimacies of the marriage bed in such cases as the present and if refusal of intercourse could constitute desertion it might do so if it were tolerated only on rare and exceptional occasions. The husband's petition therefore failed before their Lordships' House, as it had failed at the first instance and in the Court of Appeal.

¹ *Weatherley v. Weatherley* 1947 1 All ER 563
- *Jackson v. Jackson* 1924 P 19

The 1947 edition of the *Register of Speech Therapists* has just been published. The register is arranged in geographical order and includes three groups—practising, non-practising and retired speech therapists. Medical practitioners may obtain a copy free on application to the Registrar, Board of Registration of Medical Auxiliaries, British Medical Association House, Tavistock Square, London, WC1.

The Services

Majors A H MacC Eaton and G A W Neill, R.A.M.C. have been awarded the Efficiency Decoration of the Territorial Army. The Prince Regent of Belgium has conferred the Croix de Guerre 1940, with Palm upon Captain R L Rees R.A.M.C., in recognition of distinguished services in the cause of the Allies.

The President of the Czechoslovak Republic has conferred the Order of the White Lion, Third Class, upon Major General (temporary) Sir Henry L Tidy, KCB, late R.A.M.C. and the Medal for Merit, First Class, upon Lieutenant Colonel H Ross, CIE OBE, IMS, in recognition of distinguished services in the cause of the Allies.

The President of the U.S.A. has conferred the following decorations in recognition of distinguished services in the cause of the Allies.

Legion of Merit Degree of Commander—Major General W C Hartgill, CB, OBE, MC, KHS late R.A.M.C.

Legion of Merit Degree of Officer—Brigadier (local) D B McGregor, OBE, R.A.M.C.

Bronze Star Medal—Lieutenant Colonel (temporary) A J King and Major (local) H G McQuade, R.A.M.C.

Medal of Freedom with Bronze Palm—Major (local) W J Wiles R.A.M.C.

DEATHS IN THE SERVICES

Major-General O L ROBINSON died at his home at Walton-on-Thames on May 21 at the age of 80. Oliver Long Robinson was educated at Trinity College, Dublin, where he was demonstrator of anatomy. He qualified in medicine in 1890, and a year later joined the R.A.M.C. and was secretary and registrar of the Royal Victoria Hospital, Netley, for a time. He saw active service in the Near East during the 1914-18 war, having been promoted to lieutenant colonel in 1913. He was promoted to colonel and appointed an honorary physician to the King four years later. He was mentioned in dispatches and made a C.M.G. in 1916 and a CB in 1919. In 1923, the year following his promotion to the rank of major general, he was appointed Director of Medical Services in India, a post held alternately by officers of the British and Indian services. He retired from this position and from the Army in 1927. He was appointed colonel commandant of the R.A.M.C. in succession to Lieutenant General Sir Charles Burchfield in 1932. He retained this office until 1937. General Robinson had been a member of the British Medical Association for over fifty years. He was a member of the Council in 1908 and at different times had served on the R.A.M.C. subcommittee and on other central committees.

Medical News

The next meeting of the Middlesex County Medical Society will be held at North Middlesex County Hospital, Edmonton, on Saturday, June 14, at 3 p.m., when there will be a demonstration of cases and a short talk by Dr Chapman on "Haemolytic Anaemia."

The annual general meeting of the Research Defence Society will be held at 26, Portland Place, London, W., on Tuesday, June 17 at 3.15 p.m., when the chair will be taken by the President, Lord Hailey, supported by Prof A V Hill, Chairman of Committee. The sixteenth Stephen Paget Memorial Lecture will be delivered by Prof G H Wooldridge, F.R.C.V.S., on "What Animals Owe to Experimental Research."

The Middleton and North Manchester Medical Society announces that a golf competition, open to all members of the British Medical Association in the Manchester, Oldham, and Rochdale Divisions will be held on Wednesday, June 18. Particulars may be obtained from Dr James A Strachan, 566, Broadway, Chadderton, Lancs.

The Medical Women's International Association will hold its fifth congress at Amsterdam from June 24-30. At the scientific meeting on June 25 there will be a discussion on the "responsibilities of medical women in world reconstruction."

An English surgeon's bleeding bowl in solid silver with a pierced triangular handle of 1682, a silver medicine spoon with lid and spout of 1810, and ancient pottery medicine spoons from China will be among the exhibits at the Antique Dealers' Fair at Grosvenor House, Park Lane, London, W., from June 11 to 27.

On May 31 the headquarters of the Greater London Blood Transfusion Service were transferred to 10, Collingham Road, S.W.5 (Tel Frobisher 6477/8 (2 lines), day and night).

'Theamin'

For Cardiac and Asthmatic Conditions

Theamin' brand Theophylline Mono-ethanolamine is a valuable therapeutic agent in the treatment of disease of the coronary arteries, whether the cardiac disability takes the form of congestive failure, paroxysmal dyspnoea or angina of effort. Administration is followed by an increase in both coronary flow and cardiac work.

The relaxing effect on the bronchial muscle in minimal dosage, has proved of definite value in the treatment of asthmatic conditions.

Supplied in 'Pulvules' brand filled capsules in three strengths—1 gr (No 283), 1½ grs (No 233), and 3 grs (No 225). Packed in bottles of 40 and 500.

MERSALYL B.D.H.

The Standard Mercurial Diuretic

The use of Mersalyl B D H is indicated for the relief of acute oedematous conditions if it is reasonably certain that there is no severe renal impairment and when the administration of a diuretic over prolonged periods is necessary. When cardiac action is impaired, premedication with digitalis may be advisable.

Mersalyl B D H conforms with the specification for Mersalyl B P and is issued in solution (Injection of Mersalyl B P) in ampoules, in tablets (0.08 grm) for oral administration and in suppositories (0.4 grm) for rectal use. Further information will be supplied on request.

THE BRITISH DRUG HOUSES LTD LONDON N 1

Mrs F 27b

In the emergency treatment of gastric disorders, promptness in action of the antacid prescribed is all important in relieving pain and distress. Recognised as an emergency measure in such conditions 'BiSoDoL' owes its value to the rapidly-acting combination of bismuth subnitrate, magnesium carbonate and sodium bicarbonate. In addition it contains enzymes, pepsin and diastase, which materially assist during the period of impaired digestion. Pleasantly flavoured with oil of peppermint, it is readily acceptable to the most fastidious patient.

FORMULA

Bismuth subnit., Mag., carb. lev., Sod bicarb., Pepsin, Ol. menth. pip.

BiSoDoL Limited, Chancery Street, London W.C.1

"R Insulin — Boots"

WHEN the prescription is for Insulin, Protamine Zinc Insulin, or Globin Insulin (with Zinc), and the purest, most effective, potent Insulin is required, prescribe INSULIN—BOOTS. Boots Pure Drug Co. Ltd. have been pioneers in the manufacture of Insulin for the past quarter of a century.

ACID MILKS IN INFANT FEEDING

The wealth of buffer substances in milk results in the absorption of considerable quantities of acid in the digestive tract. In certain cases it is reasonable to give the infant the kind of nourishment which necessitates the least effort and controlled acidification offers a means of reducing demands on the secretory functions. In view of the varied nutritional needs of infants requiring acid milk the following range of products is available—

BEURLAC

A buttermilk in powder form useful for infants suffering from gastric disorders.

PROLAC

Of approximate half cream fat standard but with increased protein as required in gastro enteritis.

LACIDAC

HALF CREAM

An intermediate grade for less severe cases and for graduation to normal feeding.

FULL CREAM

Suitable for long term use or as a final stage of graduation to normal feeding.

SEPARATED

Almost fat free. Invaluable in cases of fat intolerance.

★ Particulars of these and other Cow & Gate preparations for specialised infant feeding will be gladly forwarded on request.

DERIPHYLLIN

THEOPHYLLIN and DI-ETHANOLAMINE

indicated in

Cardiac Decompensation, Oedema, Angina Pectoris and Cardiac Asthma

Deriphyllin has a regulating action on water metabolism and influences the cardiac mechanism. By dilating the coronary vessels and relieving any coronary spasm which may be present an improved flow of blood through the heart muscle is secured.

Deriphyllin is exceedingly well tolerated and may be given for a long time (chronic cardiac decompensation) without reaction occurring. Effect does not decrease after prolonged administration. Can be usefully combined with the organic mercurial diuretics. Not contra-indicated in renal disease.

Deriphyllin-Strophanthin is indicated for all cases of heart failure.

Available in liquid form for oral use
ampoules and suppositories

Literature and samples on request

CAMDEN CHEMICAL COMPANY LIMITED

NORTHINGTON HOUSE, NORTHINGTON STREET
LONDON, W.C.1

'Franol' contains ephedrine for relief of bronchial spasm, theophylline as a cardiac stimulant, and Luminal as a sedative.

Clinical experience in allergic asthma indicates that 'Franol' has advantages over ephedrine and theophylline prescribed singly.

Supplied in packings of 20, 100 and 500 tablets.

The annual general meeting of the British Association of Urological Surgeons Home and Overseas will be held at the Royal Faculty of Physicians and Surgeons, 242, St Vincent Street, Glasgow, on Friday and Saturday, June 13 and 14. The provisional arrangements are as follows: June 13, 10 a.m., business meeting, 11 a.m., (a) short papers, (b) films, 2 p.m., operating sessions, 5.30 p.m., Reception by the Principal, Sir Hector Hetherington, at the University, 7.15 p.m. for 7.45 p.m., Association dinner at Central Hotel (Tickets, approximately 17s 6d each, exclusive of wine). June 14, 9.30 a.m., at the Faculty Hall, discussion on 'The Treatment of Serious Tumours of the Bladder,' to be opened by the President, Mr R Ogier Ward, 2 p.m., short papers and films. Members should make their own hotel arrangements direct, mentioning that they are members of the association. Any member in difficulty over accommodation is invited to write to the local secretary, Mr W S Mack, 20, Royal Terrace, Glasgow, C3.

Mr Anthony Eden was the guest of honour at the Annual Dinner of the University of Birmingham Medical Society, which was held on Friday, May 9. Other guests included the Lord Mayor and Lady Mayoress of Birmingham, Mr Sydney Vernon, Pro Chancellor, Dr Raymond Priestley, Vice Chancellor, Mr Newton, Treasurer of the University, Sir Leonard Parsons, Dean of the Faculty of Medicine, and other members of the University Council. The chair was taken by the President of the Society (Prof A C Frazer).

Donal Sheehan, M.D., D.Sc., professor of anatomy and lately acting dean of the New York University College of Medicine, has been appointed general director of the Commonwealth Fund, in succession to Mr Barry C Smith, who will retire on Sept 1.

As already announced the Fourth International Cancer Research Congress will be held at St Louis, Missouri, from Sept 2 to 7, under the joint auspices of the Union Internationale Contre le Cancer and the American Association for Cancer Research. Headquarters will be at Jefferson Hotel, 415, North 12th Street, St Louis 1, Mo., U.S.A. A programme is being drafted to cover the general biology of cancer, aetiology (viruses, chemical carcinogens, hormones, and environmental factors), biochemistry, radiotherapy and the development of nuclear physics, chemotherapy, and various clinical aspects. Further information concerning the congress may be obtained from Prof Alexander Haddow, M.D., Chester Beatty Research Institute, The Royal Cancer Hospital (Free), Fulham Road, London, SW3.

The Secretary of State for India and for Burma has appointed Brigadiers S M Hepworth, M.B., Ch.B. (Radiologist), G W Bamber, M.D., FRCP (Dermatologist), E E Prebble, M.B., Ch.B. (Venereologist), D McAlpine, M.D., FRCP (Neurologist), E A Bennet, M.D. (Psychiatrist), H K Ashworth, M.B., Ch.B. (Anaesthetist), The Hon G F O Bridgman, M.C., FRCS (Ophthalmologist), Grant Massie, CBE, M.S., FRCS (Surgeon), and J D S Cameron, CBE, M.D., FRCP (Physician), to be Honorary Consultants to the India and Burma Offices in recognition of their valuable service as Consultants to GHQ, India, during the war.

On the appointed day for the National Health Service the Vaccination Acts will cease to have effect and the compulsory vaccination of infants against smallpox, as well as the functions and appointments of public vaccinators and vaccination officers, will come to an end. The powers under which local authorities now undertake diphtheria immunization will also cease. From the appointed day local authorities will be solely responsible for making arrangements with medical practitioners for free vaccination and diphtheria immunization for all in their area who desire these services. The present effort at securing immunization of children under the age of 5, and especially of infants, should continue, and it is thought that local authorities will have only to review carefully existing arrangements in order to ensure that they are adequate. Supplies of diphtheria antitoxin will be made available through the hospital service, and its administration will be within the terms of service of medical practitioners providing services under part IV of the Act. The Minister of Health intends publicly to encourage vaccination and revaccination against smallpox, and invites the co-operation of all local authorities. In addition if a local authority on the advice of its medical officer of health wishes to make arrangements with regard to any other disease the Ministry of Health will consider its proposals. General practitioners performing vaccination or immunization under the local authority's arrangement will be entitled to a fee which will be fixed by negotiation with representatives of the profession. The Ministry of Health will provide vaccines and prophylactics free of charge.

The Council of the Royal Society of Arts has awarded the Albert Medal to Sir Robert Robinson for his outstanding contributions to the advancement of organic chemistry, in particular his work on antibiotics.

Sir Lionel Whitby, Regius Professor of Physic at Cambridge University, has been elected Master of Downing College.

The British Empire Leprosy Relief Association announces that, following the retirement of Dr Ernest Muir, Dr Gordon A Rytte has been appointed Medical Secretary of the Association.

Dr W N MacLay has succeeded Dr Ronald Jarman as the President of the Chelsea Clinical Society.

The Royal Medical Foundation of Epsom College announces that Henry Duncalfe Annuities of £30 per annum each for spinsters in need of assistance will shortly be awarded by the Council. Candidates must be daughters of registered medical practitioners and must have attained the age of 50 years. Pensions for impecunious medical practitioners or widows of medical men, and Foundation Scholarships providing education, clothing, and maintenance free of cost for the necessitous sons of medical practitioners, are also available from the funds of the Foundation. Forms of application for the above annuities, pensions, and scholarships may be obtained from the secretary, Epsom College, Surrey.

EPIDEMIOLOGICAL NOTES

Smallpox

Since the beginning of the year information concerning 59 confirmed cases of variola major has reached the Ministry of Health. This compares with 56 for the whole of 1946, which was the highest incidence since 1934 (179 cases, mainly variola minor). These cases arise from two distinct sources. The first which was not identified, resulted in 15 cases in two generations in a common lodging-house and public assistance hospital at Grimsby (Lincs.) with dates of onset between Feb 16 and March 2. The second source was a highly modified attack in a soldier flown home from India on compassionate leave. He developed the disease at Bilston U.D., Staffs., on March 2 after landing in England on Feb 23.

Cases in direct succession to these two sources are still arising. The present outbreak at Barnsley, in the West Riding of Yorkshire, is almost certainly related to the Grimsby episode. The disease introduced from India continues to occur in Bilston and in the adjacent urban district of Coseley. Associated with the Grimsby source there have been foci at Stepney M.B. (London), 2 cases in two generations, Scunthorpe B. (Lincs.), 7 cases in two generations, and Doncaster B. (Yorks.) 1 case, but these appear to have been eradicated.

In connexion with the Bilston source, a single case occurred in Birmingham on May 1. Three cases in two generations at Sheffield may also have been associated with Bilston.

Barnsley—The first generation numbered 5 cases (3 deaths) at Barnsley and 1 at Bermondsey. There has been no spread from this latter case, doubtless as the result of the prompt action taken by a practitioner who diagnosed the disease at sight on the first day of rash. The second generation at Barnsley so far numbers 4 cases detected since May 29. They are in the line of contact either at the common lodging-house (24A Doncaster Road) or at St Helen's Hospital and do not indicate that the disease is out of control. The only alarming feature is that some of the common lodging-house contacts have not been traced and may give rise to other foci, particularly along the tramp routes across England through Lincolnshire, West Riding of Yorkshire, Derbyshire, Cheshire, and Lancashire.

Bilston and Coseley—The mother and sister of an unvaccinated girl who died on May 16—four days after onset—were removed to the smallpox hospital on May 31 (onsets May 29 and 30). The mother of a kitchenmaid at Moxley Infectious Diseases Hospital, removed from her home in Coseley on May 19, has now developed the disease (onset May 28, rash and removal May 30).

Discussion of Table

In England and Wales there were increases in the notifications of measles 2,544, diphtheria 49, and smallpox 10. A small increase was recorded for scarlet fever 26, and there were decreases in the incidence of whooping cough 102 and of dysentery 45.

Only small variations occurred in the local trends of scarlet fever. The rise in the incidence of diphtheria was due to small increases throughout the country and no large change occurred in any locality. A small decrease in the notifications of whooping cough was recorded in most areas, the only exception of note was an increase of 60 in Surrey. The largest rises in the notifications of measles were Yorkshire West Riding 316, Derbyshire 231, Glamorganshire 224, Warwickshire 184, Kent 165, Surrey 151, Staffordshire 105, Gloucestershire 104, and Cheshire 100.

The fall in the number of cases of dysentery was due to the experience of Lancashire with 47 fewer cases than in the preceding week. Of the 25 cases of dysentery in Lancashire 19 were notified from Prestwich M.B.

With the exception of the 13 cases notified five weeks ago, the returns of smallpox were the largest of recent years: the notifications were Yorkshire West Riding Barnsley C B 6, Staffordshire Bilston M B 4, Warwickshire Birmingham C B 1, London Bermondsey 1 (a contact from Barnsley).

In Scotland increases were recorded in the notifications of measles 29 cerebrospinal fever 18 scarlet fever 17 and diphtheria 11. The rise in the incidence of cerebrospinal fever and of diphtheria occurred in the western area: half the total notifications of these diseases in the country were recorded in Glasgow.

In Eire a rise occurred in the notifications of measles 30 whooping-cough 23 and scarlet fever 13. New outbreaks during the week were measles at Wexford, New Ross U D 17 and whooping cough at Mayo Clarcormorris R D 12.

In Northern Ireland measles declined to 14, the lowest total for recent months but scarlet fever increased by 12.

Quarterly Returns for Northern Ireland

The birth rate during the December quarter was 21.8 per 1 000 being 0.3 above the average of the fourth quarters during 1941-5. Infant mortality was 53 per 1 000 registered births and was 17 below the average of the five preceding December quarters. Maternal mortality was 2.9 per 1 000 births, being 0.3 above the five years average. The general death rate was 11.8 per 1 000 and was 0.6 above the rate for the corresponding quarter of 1945 but 0.8 below the average of the five preceding fourth quarters. There were 204 deaths attributed to respiratory tuberculosis and 54 to other forms of tuberculosis, these were 7 above and 10 below the average of the fourth quarters 1941-5. There were 67 cases of typhoid fever notified in Armagh city and county during the quarter. This outbreak of typhoid fever was due to contaminated milk, and altogether 77 cases, of which 5 were fatal, were traced.

Quarterly Returns for Eire

During the December quarter a birth rate of 20.7 per 1 000 was recorded. Infant mortality was 62 per 1 000 registered births and was 10 below the rate for the fourth quarter of 1945. Maternal mortality was 1.5 per 1 000 registered births, being 0.1 below the rate for the corresponding quarter of the preceding year. The general death rate was 12.5 per 1 000 and was the lowest fourth quarter rate since 1941. For the whole year the birth rate was 22.6 per 1 000 and was 0.2 above the rate for 1945. Infant mortality was 63 per 1 000 and was the lowest rate ever recorded. The general death rate was 13.9 per 1 000 and was 0.4 below the rate for 1945. Deaths from diphtheria were 101 below the total for 1945. There were 903 deaths attributed to diarrhoea and enteritis of these 461 were registered in Dublin C B. The death rate for pulmonary tuberculosis was 0.9 per 1 000 and 0.2 for other forms, the rates for 1945 were 0.9 and 0.3 respectively.

Austria

The following table is an extract from the April issue of the *Monthly Report of the Allied Commission for Austria* (British Element) comparing the rates for 1939 with those of 1945 and 1946 for Austria and Vienna.

	1939	1945	1946
Birth rate			
Austria	20.8	13.6	15.2
Vienna	14.8	9.6	10.3
Infant mortality			
Austria	69.6	164.9	77.0
Vienna	12.6	188.2	78.8
Death rate all causes			
Austria	15.3	23.4	14.2
Vienna	16.4	32.8	19.0
Death rate tuberculosis			
Austria	0.95	1.28	0.99
Vienna	1.22	2.62	1.95

A comparison of the figures for 1939 with those for 1945 suggests that Vienna fared rather worse during the war than the whole of Austria. The death rates from all causes and from tuberculosis in 1946 fell to pre-war levels for Austria but remained considerably above pre-war level in Vienna. The very low infant mortality recorded for Vienna in 1939 is an error: the infant mortality in this city during 1937 and 1938 was 71 and 51.

Week Ending May 24

The notifications of infectious diseases in England and Wales during the week included scarlet fever 782 whooping cough 1 879 diphtheria 197 measles 12 830 acute pneumonia 557 cerebrospinal fever 65 dysentery 47 acute poliomyelitis 11, smallpox 8 paratyphoid 6, typhoid 3.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended May 17.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for: (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland.

Figures of Births and Deaths recorded under each infectious disease are for: (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping cough are not notifiable in Scotland and the returns are therefore an approximation only.

† Includes primary form for England and Wales (London (administrative county) and Northern Ireland).

‡ Includes puerperal fever for England and Wales and Eire.

Any Questions ?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Oranges, Bananas, and Dates

Q—(a) Oranges and bananas are shipped unripe from the countries of origin: this often means that only partially ripe fruit is distributed in this country. Family practitioners are kept busy treating children glutted by such fruit. Has not sentiment outweighed dietetic discretion in this exclusive allocation to children? (b) What is the nutritional value of the date? What vitamins are involved and are they of any value?

A—(a) Oranges and bananas are allocated as follows. Oranges on any ration book, what is left over of the allocation after five days, without ration books. Bananas on green ration book (R B 1—up to 5 years) and on blue ration book (R B 2—from 5 to 18 years) only. Oranges are therefore not allocated exclusively to children. The quantity of bananas distributed is so small that unless their parents have access to irregular sources, children have little chance of being glutted.

(b) The main value of dates, apart from adding to the variety of the diet is to provide calories, 100 g provides about 240 calories, mainly as sugar. Estimates of the amounts of vitamins vary. According to *Nutritive Values of War-time Foods* (H.M. Stationery Office, 1945) the vitamin-A potency is 100 i.u. per 100 g, and no vitamin B₁ or C is present. According to other estimates the vitamin A is higher, but is still not enough to make an important addition to the daily supply. The vitamin B₁ is enough for the metabolism of the carbohydrate of the date, and the amount of riboflavin in 1 oz (28 g) of dates is about one third of that in 1 oz. of milk.

Palpitations

Q—What is the treatment for palpitations? Standard text books dismiss this condition in a few lines.

A—There can be no uniform treatment for palpitations. It is not a morbid entity but a symptom, and occurs in a wide range of conditions. The cause must first be determined. In young people it rarely represents heart disease, in older subjects it may be associated with arrhythmia, hypertension, or heart failure. It may be due to toxic or infective conditions or it may follow the administration of drugs. Mediastinal tumours or abdominal distension may provoke palpitation by mechanical means. The symptom is common in nervous people, in whom it may cause real discomfort or even a painful sensation. It is not of itself an indication of heart disease, but fear of this may aggravate the symptom through anxiety. Patients complaining of palpitation should be thoroughly examined to exclude any organic cause, and this in itself is part of treatment, as it goes far in gaining the confidence of the patient and lending weight to the opinion and advice given. Any underlying cause—such as anaemia, oral sepsis, or fatigue—should be corrected. If heart disease is present it should be treated appropriately. If it is absent, firm reassurance on this point should be given. Palpitations due to overaction of the heart may be alleviated by small doses of bromide or phenobarbitone given twice daily. Palpitation associated with premature beats is most likely to be relieved by checking the arrhythmia with a pill containing quinine sulphate gr 3 (0.2 g) with ext. nuc. vomicae gr 1/4 (16 mg) thrice daily.

Enterogastrone

Q—What is known in this country of the preparation enterogastrone?

A—The story of enterogastrone begins as long ago as 1929, when three Chinese workers—Feng Hou and Lim—demonstrated the presence in the intestinal mucosa of a substance which inhibited gastric secretion. Kosaka and Lim gave this substance the name 'enterogastrone' in 1930. The inhibition of gastric secretion by olive oil was shown to be effected

through the action of enterogastrone. Additional work was done by Ivy and Gray in Chicago, and Gray described a substance in the urine which depressed gastric secretion, he called this 'urogastrone'. Despite the passage of eighteen years no practical application of enterogastrone or urogastrone has been devised. It might be worth consulting an annotation in this *Journal* (Aug 10 1946 p 204), in which Morrison's work on hog's stomach is described. An extract of the mucosa and submucosa of fresh stomach—not intestine—appeared to protect dogs from the peptic ulcers induced by the administration of yellow cinchophen.

Treatment of Epilepsy

Q—A single woman aged 25 has suffered from epileptic fits for the past seven years. These were at first controlled by bromides, then, because of repeated attacks by a combination of bromide and phenobarbitone. This succeeded for a year, then there were a series of attacks despite increase of drugs. Hydantoinates then proved satisfactory for a year or two but were followed by a rapid succession of fits. A combination of phenobarbitone and hydantoinates had a similar result. Can you recommend further treatment?

A—Combinations of phenobarbitone and hydantoinates in carefully balanced doses are capable of controlling the great majority of cases of major epilepsy. With regard to the latter it may be necessary to give full doses—that is, 1½ gr (0.1 g) four times in the twenty-four hours. As this dosage is near the level of toxicity it cannot be increased. If the attacks are of the petit mal variety then drugs of the 'tridione' class will be indicated.

Oedema at High Altitudes

Q—When she climbed Skiddaw eight years ago a woman's hands became so swollen that she was unable to close them. On the descent the swelling subsided. She has a tendency to hay-fever and two of her relatives are asthmatics. In view of this history, is there a possibility of serious consequences (such as oedema of the glottis) arising from a visit to the Swiss mountains and is there any preventive treatment?

A—It is most unlikely that the lowered barometric pressure was responsible for the symptoms which occurred in climbing Skiddaw (a nearly equal fall in barometric pressure may occur at sea level in severe winter depressions). The anoxia experienced would be difficult to detect and, as a physiological stress, negligible in comparison with the other stresses of such an expedition. It is therefore not considered that this is a contra-indication to a visit to Switzerland, so long as only moderate altitudes (up to 5000 feet) are attempted and so long as the patient follows a normal regimen suited to her age and history.

Stilboestrol to Control Libido

Q—Can stilboestrol be used to control excessive libido in the male? As oestrogenic treatment of carcinoma of the prostate is followed by atrophy of the genitalia and loss of sexual function it occurred to me that similar treatment may control an undue degree of spermatogenesis in the younger male.

A—Yes, it can even to the point of complete suppression. Its use is justified in extreme cases, temporarily or intermittently, but it interferes with the structure of the testis, and therefore intervals are required for recovery. It is difficult to say if a dose can be found which inhibits functionally without structural damage, or to know clinically when such a dose is arrived at, and it may be that the 'all or none' law operates. Incidentally, libido is related to interstitial cell function, and not to the degree of spermatogenesis.

Otosclerosis and Malaria

Q—A patient became hard of hearing after an attack of malaria and subsequent bouts increased his deafness. Investigation revealed otosclerosis, there were no family history and no quinine deafness. Did the malaria cause the onset or increase the deafness of otosclerosis? What would you advise?

A—It may be confidently assumed that the malaria increased the deafness of otosclerosis. The cause of the latter is inborn,

not acquired post natus. Deafness is always more marked during fatigue or illness because the subject is then unable to make the extra effort normally needed to overcome his handicap. Nothing is at present known which will arrest the progress of the disease. The increase of deafness may be offset by learning to lip read and by the use of a valve amplifier hearing aid. Recently fenestration of the labyrinth has been revived, this subject was reviewed in the *Journal* of Sept. 29, 1945 (p. 430). The present-day technique has given much better results in selected cases, though how lasting the improvement will be remains to be seen.

Arterial Thrombosis

Q—A man aged 68 was suddenly awakened with severe pain in his left calf rubbing eased it but the calf remained tender and painful for about a fortnight. Since then he has had intermittent claudication in the leg after walking some 100 yards and numbness and ungluing of the foot. X-ray examination shows scattered calcification of the arteries in both legs. How would you treat this condition?

A—This account leaves no doubt that thrombosis of one of the main arteries has taken place. The most common sites for such obstruction are the femoral artery in the mid-thigh, and the popliteal artery. The symptoms suggest that in this case the block was somewhat lower. The therapeutic indication is to try to increase the collateral arterial circulation in the leg, this may be done by intermittent venous occlusion, by intravenous injections of saline or plasma, or by lumbar sympathectomy. For the precise indications and details the standard textbooks should be consulted.

Penicillin and Bismuth in Syphilis

Q—A man and wife who contracted syphilis twenty five years ago have just completed a prolonged course of arsenic and bismuth they are now symptom-free but serologically still positive. They want to try penicillin. What course of this drug plus bismuth and arsenic would you recommend? At what stage of the arsenic-bismuth treatment should the penicillin be given and what is the expectation of cure?

A—A good deal depends on what is meant by a "prolonged" course of arsenic and bismuth, and how soon treatment was started after infection. Assuming that each patient has received at least 25 g. of neoarsphenamine or its equivalent and 10 g. of bismuth metal, and that the patients have reached the age of 50 or thereabouts, no further treatment is necessary provided their spinal fluids are negative. Penicillin is not recommended since this antibiotic is not very effective in reversing resistant serum reactions. However, if the patients insist on its use, a total dosage of about 10 mega units is advised. This may be administered by daily injections of 300,000 Oxford units contained in a slow release vehicle, bismuth may be given concurrently in doses of 0.25 g. once a week for ten weeks, there is no object in giving arsenic. The expectation of cure, in the sense of reversing the serum reactions, is poor, but, provided their spinal fluids are negative and there is no evidence of cardiovascular disease, there is no reason to suppose that syphilis will materially shorten the life of either patient.

INCOME TAX

All inquiries will receive an authoritative reply but only a selection can be published

Expenses arising from Requisitioning of Premises

D B was called up for naval service in August, 1939, and served until April, 1947. His house has been requisitioned and requests to de-requisition it have proved fruitless. In the meantime his family have to live in the country and as he holds an appointment in London he is put to considerable expense in visiting his family. Can any deduction be claimed in these circumstances from his income tax assessment?

*No, with the possible exception of the fixed £10 special 'war' allowance. The expense would not be regarded as being incurred in carrying out the duties of his employment but rather in his private capacity as head of a family.

Letters and Notes

Vitamin B₁ for Herpes

Dr S J Gross (Chirala, British India) writes. With reference to the treatment of dermatitis herpetiformis as recommended by Dr R. Milton and Dr T H K. MacLaughlin (March 22 p. 402) I should like to suggest another method which to my knowledge has not been described yet. It has been suggested that in herpes the virus passes down the sensory nerves to the skin and produces the lesions there. Vitamin B₁ has been recommended and has been used in the treatment of herpes with doubtful results. Herpes is due to a localized nervous irritation and not to a systemic affection. Therefore I thought that a local application of thiamine might be more successful, and that when applied locally the vitamin B₁ might proceed along the nervous pathways from the skin to the affected nerve ganglion. The following mixture was used for the topical application: 1 ml. of thiamine hydrochloride containing 50 mg. dissolved in 3 ml. glycerin. This medication is applied three times daily to the skin lesions. Soon after the first application the patients notice a soothing sensation, and after the second application they experience a great relief, the itching ceases, and the pains disappear. The following cases may serve as illustrations. (1) A woman 8 months pregnant was admitted with a painful herpes of the lower lip. A number of local applications had been tried unsuccessfully. I painted the lip with vitamin B₁ glycerin. After the first application she felt better and was able to bear touching of the lesions. After the second application it was noted that the blebs started to burst and to dry up. Patient had no pains any more and was able to eat again. Simultaneously the swelling of the lip began to decrease, and on the next day patient was perfectly well and went home. (2) A nurse 25 years old was admitted with a very painful herpes and herpetiform dermatitis of the buttock and of the inguinal area. On account of the pain she was given morphine injections, and she had different local applications with no improvement. On the third day of the eruption vitamin B₁ glycerin was applied locally. After the first day she had still some pain, but the itching had decreased. After the second day of local applications pain and itching had disappeared. No new vesicles had formed, and the old eruptions began to dry up and to heal. For the last six months I have been using the topical application of vitamin B₁ glycerin in these and a number of other cases with the same good results. Thus I have come to regard vitamin B₁ in glycerin as a specific for the treatment of herpes and of herpetiform manifestations. No other treatment was given concurrently.

Nocturnal Enuresis

Mr H P WINSBURY WHITE (London, W 1) writes. The answer to the question on enuresis (May 24, p. 749) prompts me to add that the urethra should be carefully examined in obstinate cases. It is essential that urethroscopy is included. The latter procedure can be carried out in all children with this complaint. Residual urine from bladder-neck fibrosis, granulomatosis or polypoid changes in the posterior urethra, generalized or localized contractions of the anterior urethra, all play their part and are easy to remedy, moreover the enuresis improves if the local pathology is properly treated. The examination and treatment which I have carried out of several hundreds of these cases along these lines have convinced me of the importance of this approach. If any one of your readers who has not the facilities for urethroscopy in children, but who has the means of making this examination in adults wishes for conspicuous evidence of urethral pathology in association with enuresis, let him seek out and examine several cases in which the incontinence has persisted into adult life, for urethral changes when present are usually very obvious in such patients.

Tuberculin Tests Correction

In the *Journal* May 31, at p. 793, under the heading 'Tuberculin Tests' the statement 'If no reaction is obtained after two hours' should have read 'after two days'.

THE MEASUREMENT OF HUMAN SKILL^{*}

BY

F C BARTLETT, CBE, FRS

The Nature of Skill

Perhaps the beginnings of skill are to be found in the graded response. As has often been pointed out, it is a characteristic of a good many very early and very simple kinds of reaction to be of the "all or none" type. There is some evidence, which will have to be considered later, that a "trigger-like" character of effector response, in which nothing happens until a stimulus exerts a certain "pressure" and nothing more happens even when the stimulus exerts much more "pressure," remains to play a little regarded or understood part in quite complicated expressions of mental and bodily behaviour. But it is certainly the case that most of our everyday actions seem to be more or less accurately graded in amount, direction, duration, and other respects in agreement with corresponding variations in the stimuli required to produce them. And such graded action, however simple it may be, has at least one of the fundamental marks of skill—an effector response is not merely set off by a receptor function but is guided and determined by it. The receptor functions that are important in the case of skilled behaviour, however, are, I think, never those alone which indicate changes in shape or volume of muscle. They are always of that kind which claims to register something that is going on in the outside world. So they come to be particularly identified with the operations of the special senses, and especially of those distance receptors which are the basis of tremendous development of the central nervous system. Skill, then, whether bodily or mental, has from the beginning this character of being in touch with demands which come from the outside world. This is what gives it its strong cognitive nature and makes it possible to use phrases such as the one coined by Elliot Smith—"the intellectual respectability of muscular skill."

Whenever we talk of skilled behaviour, however, we mean much more than this simple and basic fact of detailed determination by receptor function. We mean behaviour in which a good many different receptor and effector functions are interlinked, all joined in the pursuit and achievement of some task which, when it is achieved, seems at first sight as if it can be discussed, criticized, evaluated, and even measured in its own right, apart from the means used to bring it about.

Let us consider a few instances of what everybody agrees to call skilled performance. Since it was wartime experience which revived for me a long-standing interest in the nature and conditions of human skill I will begin with two cases which have been a subject of much experiment in recent years.

The bomb-aimer in the aircraft, peering intently through his bomb sight, watches and interprets a series of visual cues coming from successive clusters of landmarks some of which are of predominant importance. From time to time he issues directions to the pilot and receives the answering confirmation. He judges at length that the series has reached its culmination, presses his bomb switch, and the operation, so far as he is concerned, is complete. If the bomb falls within the effective target area the task may be adjudged well and truly done. The visual cues predetermined and so laid out and seen that one leads to the next and does not merely precede it, may differ every time, though their significant order remains relatively the same. The attendant effector responses may differ also right up to the final pressing of the switch. Yet the criteria of the success or failure of the task seem to remain constant.

The pilot, airborne and flying on his instruments, must be alert to an almost incredibly complex mass of incoming signals—visual, auditory, tactile, thermal, proprioceptive. These, at the appropriate moments, his actions must match. The whole performance, from take-off to landing, is a long-drawn-out interlinkage of receptor and effector functions, forming a veritable series and not merely a succession each item a step to another step, right to the end. Yet it has often been claimed that an informed observer sitting by the pilot, knowing nothing, or next to nothing, of the terrific play of his senses and muscles and mind can criticize, rate, and measure his achievement. More than this is sometimes claimed, for it is said that an observer who never sees either the pilot or his aircraft, but is merely supplied with an objective record of what the machine has done, especially during critical manoeuvres, in the course of its flight, can with reasonable success measure or assess the pilot's skill. Even beyond this, though possibly with some exaggeration, it is often considered that the skill of the pilot can be correctly criticized and judged if nothing more is available than an accurate objective record of the landing.

And we could take any other case of admitted human skill and find that exactly the same sort of fundamental considerations apply. The good player of a quick ball game the surgeon conducting an operation, the physician arriving at a clinical decision—in each case there is the flow from signals interpreted to action carried out, back to further signals and on again to more action, up to the culminating point of the achievement of the task. From beginning to end the signals and actions form a series, not just a succession. The items in the series have, within wide limits, a fluid order and varying qualities. Moreover, there are always plenty of people—we all do it—who are willing to pronounce a verdict on the achievement alone, sizing it up, placing it in

^{*} The first of two Oliver Sharpey Lectures given at the Royal College of Physicians of London on Jan. 21.

relation to other achievements of the same sort. Can it be that the measure of skill is really a measure of the achievement which skill attains?

As soon as that question is put difficulties will occur to everybody. If the bomb drops in the effective target area once, and the next fifty times drops outside it, in ordinary speech—which may be fickle, but is generally of some psychological interest—we call it a lucky shot. It is clear that measure by achievement must have a lot of achievements to work on, and even then is statistical only. This is an upshot which is openly accepted, or ought to be, by all those who pin their faith to those measures of skill by tests which have become enormously popular of late. I cannot, within the limits of these lectures, consider this kind of measure, but it is certainly not very satisfying to the experimentally minded, who if they wish to avoid or supplement it are forced back upon studies internal to the skill performance itself.

There appears to be something level and uniform in skill performance which is consistent with considerable variations in skill achievement. W. R. Hammond,* a witness of some merit—to speak mildly—says that his most skilled innings was one which gained him a mere 32 runs. When we search the skill performance to find what these uniform characters are and how we can use them to obtain the measures we want, we can, I think, set the problems into three main groups.

There are, first, problems of the linkage of receptor and effector functions, second, problems of the grouping and stability of the constituent items in the full performance, and finally—for we cannot really get away from the “task”—problems of the relation of achievement to means.

Each of these groups can be approached experimentally. If in attempting to describe this approach I deal in the main with work developed during the last few years in the Cambridge Psychological Laboratory, it is not from any lack of appreciation of significant developments made elsewhere, but for two main reasons. First, I cannot well help knowing more about it myself, secondly, for obvious reasons some of it could not be widely reported before, and may therefore be of greater interest to others.

Linkage of Receptor and Effector Functions in Skill Performance

There is one characteristic which crops up over and over again in descriptions of expert skilled performance. The operator is said to have “all the time in the world to do what he wants.” This has nothing to do with the absolute speed of the constituent movements, bodily or mental. These may be almost incredibly quick, or they may be leisurely and slow. What is impressive is the absence of any appearance of hurry in the whole operation. There is no jerkiness or snatching, no obvious racing to catch up in one part and forced sauntering to make up in another. The “time” that is spoken of is really “timing,” and if we could understand the simple timing mechanisms which the human body and mind must obviously be able to use, and how they work, we should have got some way, at least, towards a measure of degree or level of skill.

Perhaps this is what has made most investigators who have set out to measure skill turn to the classical reaction-time experiment. Considering that every possible skill that can be studied consists of a set of actions and reactions between receptor and effector processes, this seems a sensible thing to do. Yet it must be admitted that not one single investigation of reaction times in the classical manner, however elaborate it has been, has thrown any

important light on the problems of how to achieve a measure of skill.

The technique of the reaction-time experiment was worked out by the Dutch physiologist Donders in the 1860s. It has not been varied in any important respect since then, except in regard to instrumentation, which has of course enormously improved. Donders did not set out in any sense whatever, to investigate skill. His aim was simply to measure the time elapsing between the presentation of some simple form of stimulus and some single simple muscle response. Naturally and rightly, therefore, he chose responses which, so far as the experimental measure is concerned, literally begin and finish at the same instant. The finger lifted from a Morse key may rise an inch or a mile—it makes no difference. In any conceivable form of skill, however, circumstances of this kind do make a tremendous amount of difference. This is because a given movement has to be followed by another and the second has to be spaced correctly in regard to the first. The time we need is the total reaction time, including that required for the full completion of a given movement, and the recovery time which the organism must have in order that a successive movement should be efficiently performed. This recovery time may have to take account of latent effects produced by the original stimulus whether on the receptor or the effector side.

For example, as is well known, it can be experimentally shown that when a muscle is operating against resistance certain latent effects remain, when its operation is completed, which will automatically interfere with a succeeding reaction of that muscle, or muscle group, and perhaps with related muscle groups. More important still, very likely, every constituent action in the case of most psychophysical skills must grow out of a setting of bodily or mental posture. This posture must be reset before the succeeding movement can be effective.

Timing of Constituent Reactions

It is, I think, vitally important, if we are to understand the simple timing of constituent actions in the continued exercise of skill, to study and determine the normal limit of duration of these latent effects, of after-contraction in the case of muscle, of the after-effects of certain receptor sensory processes, and of the reset of posture required from move to move in almost all forms of bodily and mental skill. Experiments at Cambridge have recently shown, for instance, that where after-contraction is lacking or excessive certain kinds of skill—those involved in piloting aircraft—are learned with difficulty and when learned are easily broken up.

Now there seems to be a considerable amount of evidence which suggests that in general the recovery time for receptor processes is shorter than that required by effector processes. For example, a year or two ago we set out to study some of the phenomena of visual accommodation. The display consisted of a series of Landolt rings, or broken circles, with the gap north, south, east, or west, in relation to the observer. The rings were presented alternately near and far distance, and a simple four-way switch was designed by which the operator could indicate the assigned position of the gap. The time and duration of appearance of each item in the display were automatically recorded, and similarly the beginning and end of every reaction and the intervals between successive items, both of display and of response. When the operator was fully used to the situation he was allowed to determine his own preferred rate of working. His first response sets up the second stimulus, his second response the third stimulus, and so on. Naturally the preferred rate fluctuated somewhat for

* *Cricket—My Destiny* 1946 p. 128 London Stanley Paul

given operator, but not by very much. Preferred rates of different operators varied considerably. We now determine the upper tolerance limit of speed for the whole population, taking as our criterion the occurrence, and perhaps recurrence, of half a dozen closely contiguous errors or omissions. In this case, of course, the rate of exposure of the rings is determined by the experimenter. There is some evidence that the upper tolerance limit remains approximately constant for different operators at an increase of speed proportional to the preferred rate. But the most interesting result is that the study of the records shows that when the operator breaks down he is, in almost all cases, trying to respond, not to the circle that is immediately before him, but to the preceding circle, or to the second or third preceding circle. The receptor and effector series have got out of step, the latter lagging behind. We have some evidence that much the same happens in tracking a rapidly moving target, and dealing with radar displays in extremely quick sequence. And, indeed, this only confirms much common observation. In reading, the eye interprets far ahead of the voice, and if an effort is made to read exceedingly swiftly, "by whole paragraphs," as H. G. Wells used to say, it can be effective only if much of the usual effector association is short-circuited or suppressed. Perhaps the case is most striking of all when posture has to be reset. For then it is the accessory movements, of which normally the operator remains totally unconscious, which markedly and obviously go wrong. The footwork, which may settle the whole body balance, lags and sets everything else out of time. It is extremely tempting to suppose that often when this kind of thing happens, and when the operator is struggling to deal with receptor signals which are no longer present to him, these signals have got on to a rapidly accelerating phase in the curve of immediate forgetting. We have evidence in favour of this, but it is not yet conclusive.

Nothing in the whole course of the total reaction time is rigidly set. Like every other measure of human function this turns out to be a measure of range. There are limits, upper and lower, within which the timing can rapidly fluctuate and the essential adaptive spacing of actions still be maintained. Outside those limits only the skill breaks down.

To a psychologist this is singularly interesting, because most of the conditions that determine the extent of the range can at present be dealt with in psychological terms only. This is not always the case. For a simple objective increase of urgency—in speed, for example, or in the resistance opposed to movement—will be met swiftly by an almost reflex-like increase of effort. Skill that is threatening to deteriorate can, paradoxically, often be restored by an objective increase in the difficulty of the situation. Precisely the same effect, however, can be produced and on a high level more frequently is produced, in definite volition. How this is done still remains largely unknown, but it is certainly in part achieved by the suppression of flourishes which have become uneconomical, though this essentially does not mean that they always are so. That they are not can indeed be seen in the curious circumstance that on the whole it is easier to shorten than to lengthen the customary overall response time. We have many experiments which show that slowing of skill is very hard to tolerate, and I suspect that this is because suppressing flourishes is less difficult than inventing them.

Another condition which can produce shortening of response time is anticipation. Perhaps this is largely responsible for the demonstrated fact that real experts train their skill under conditions which defeat the beginner and the performer of ordinary ability. For example,

receiving and sending wireless messages at speed can be adversely affected by a steep rise of temperature and humidity. But whereas the upper limit of effective temperature for the average performer comes rather sharply at 83° F (28.3° C), the expert continues without serious disturbance for another 17° F (9.4° C). Yet the overall response times for all performers remain closely comparable under all ordinary conditions.

Finally, anything that can arrest the speedy decay of immediate memory will tend to lengthen the overall effective response times and keep receptor and effector functions sufficiently in step for long periods. The conditions which promote this seem to be largely on the display side, in the ordering of the signals for skill which have to be dealt with by the senses, and especially the distance senses. A degree of novelty just enough to combat the peripheral processes of adaptation and the central tendencies of habituation is desirable. Little is known about these conditions as yet, but it has become clear that the placing of signals, especially towards the upper and leftward parts of a visual field, their movement and direction of movement, and the utilization of contrast and colour are all of them important.

The Phenomenon of "Lowered Standard"

On the other side, and working all the time towards increased liability for items in skill behaviour to get awkwardly out of phase one with another, are adaptation and habituation, and something different from both—the curious phenomenon of "lowered standard." Like a lot of other things in behaviour, once this is defined and clarified under experimental control abundant illustrations can be found in everyday experience. This often lays the psychologist under the charge of discovering only what everybody already knows, but that kind of discovery is in fact as important for exact knowledge as any other. We first noticed the case of "lowered standard" when we were studying the kind of deterioration which can be expected to affect the skill of the air pilot who is flying on instruments for long periods without rest. The operation, like that of every other instrument reader, is essentially an exercise in the discrimination—usually the visual discrimination—of alignment and misalignment. The operator must notice the coincidence of a pointer or other indicator with, or its variation from, some mark or member of a series of marks on his instrument. For two reasons it is no use at all taking a measure of absolute visual or other spatial discrimination threshold and deducing anything from that. The observer has to respond not only to the misalignment but to the direction of it. He has not only to notice the appropriate mark on the instrument but to identify it among a number of other marks. It has been known for years that either of these requirements will push up the discrimination threshold, and if the amount of the rise depends at all on the absolute discrimination threshold their functional relations are certainly unknown. On top of this it is still no use allowing for these matters and then getting a measure of effective threshold outside of the skill in any succession of isolated graded tests. For within the skill there are always two thresholds—one a measure of what the observer can do and the other of what is treated as *worth doing*. These can, and constantly do, vary quite independently. At the beginning of exercise they normally approximate to the same value though they are never quite identical. With continued exercise, or under a variety of other conditions they diverge more and more. The threshold of discrimination—what the operator can do—is little affected, except in extreme cases, the threshold of indifference—what is treated as *worth doing*—may rise to double, treble, or

quadruple its original value. Moreover, however this standard of work is set it may be, though it is not necessarily, entirely a neurological affair. The operator may know nothing about it. He may assert that his skill is exactly as it was, and if he is stopped and his threshold of discrimination measured he may appear to be right. For a genuine measure of his skill he needs to have both these thresholds determined within the operation itself.

Results of These Experimental Studies

Let me now try to sum up the main results of these developing experimental studies of skill so far as the linkage of receptor and effector functions is concerned. By far the most important one is that no measure of isolated function can throw any light upon skill or immediate skill potentiality. The crucial point in the linkage with which we are concerned is the accurate timing of the constituent items within their series. So far as the sensorimotor characteristics of the process go it seems that the important thing is the determination of the overall response times—including the recovery time—in the march from interpretation to action and from action to interpretation. There is a tendency for effector response time to lag and for action to get out of step with signals for action. This can be arrested within limits by increased objective urgency, by volition, and by anticipation, provided it does not run very far ahead. It will be facilitated, unless special precautions are taken, by a rapid fall of immediate recall and by the automatic increase of indifference threshold. Looking at the whole matter from the point of view of classical psychological experiment, the field is now set for a thorough reorientation of the traditional study of reaction times and of the functions of latent after-impulses.

[The second lecture will appear in our next issue]

A CONCEPTION OF INDUSTRIAL HEALTH*

BY

R C BROWNE, DM, MRCP

Nuffield Professor of Industrial Health in the University of Durham, King's College, Newcastle-upon-Tyne

At any moment of time, and especially in a relatively free-thinking community, the volume of public support lent to an idea is often as important as the intrinsic novelty of the idea itself, and when the pressure of opinion surpasses a certain critical value action leaps from latency to life. The conception of industrial health now has reached this point. It is, however, always a salutary exercise, on starting a new venture, to consider whether its aims and outlook are really original, whether they represent a step in a process of thought which started long ago, or whether they are merely the return of a cyclical fashion.

Some Preliminary Thoughts

It is also appropriate now to put forward some preliminary thoughts about this new Nuffield Department in King's College, and about the methods of approach which it is intended to adopt in order to study some of the facets of this very wide problem of industrial health. But first, perhaps, the very word "health" itself requires some consideration, as we must remember that the classical conception, which the Greeks called *hygieia*, had in their day a

limited application, usually to the soundness of the body only, and now, like so many other words of like derivation it has lost caste and become our English "hygiene" with its stereotyped suggestion of soap and water, teeth and tooth-brushes, forms and files, strictly departmental thinking, and rather dull courses of lectures.

But health surely means, among other things, freedom from disease, good performance at the job, whether of mind or hand, the right rate of growth, and the happiness born of a satisfactory wholeness of existence. Moreover in their wisdom the founders of this Chair intended to indicate a breadth of interest, especially in the direction of the causation and prevention of disease, which would not have been clearly shown by the use of any other word. It is, then, worth while taking trouble to define what is meant by health, because when a new subject or a new attitude towards an old subject comes into view it is only too easy to be under a misconception about what is meant, or even to say that there is no such thing, and, indeed, the most recent attitude towards medicine, which is often thoughtlessly criticized along these lines, is that of social medicine, which some people deny exists at all, and which others even think is medicine in relation to the State.

It may, therefore, be suggested now that the field of study of our new department here may be considered to be the reciprocal and triple relation between job and health, the social state, and it is worth while noting at this point that this contrasts somewhat with a conception based upon industrial *medicine* or *disease* as usually conceived, because there is, of course, no true dividing line between industrial and non-industrial illness.

Foundations of Industrial Health

As long ago as 1670 the Italian doctor Ramazzini laid the foundation stone of industrial health with his book *De Morbis Artificum Diatriba: A Dissertation on the Diseases of Workmen*. Ramazzini was not only a bedside doctor but spent much of his time visiting workshops and mines, noting especially the conditions of work, and his conception of industrial health was wide, as shown by the later editions of his book, which included chapters not only upon the diseases of learned men but even upon the health of nuns—an investigation which we may well imagine to have taxed his ingenuity to a high degree and to have involved secret methods, perhaps including even personal disguise.

After a long interval this work was followed, in the middle of the eighteenth century, by a most brilliant practical demonstration of preventive medicine applied to a small community by the naval captain James Cook, who on a voyage which lasted more than three years, which stretched from latitude 52° N to 71° S, and which meant, therefore, going through the Tropics, lost through illness but one out of his crew of 118 men. The Royal Society appropriately marked this feat by awarding him the Copley medal for his paper entitled "The Method taken for Preserving the Health of the Crew of His Majesty's Ship the *Resolution*, during her late voyage round the world." Now Cook's outstanding demonstration, the more notable because he was a layman, was not so much due to his having made any new discoveries in the science of preventive medicine, but can be ascribed almost entirely to his making the fullest application of the principles which were known at the time, to his attention to detail, and to the fact that he had complete charge of a small and isolated community.

The next step forward in this subject came in 1831 with the publication of a book entitled the *Effects of the Atmosphere*.

* An inaugural lecture delivered at King's College on Feb. 24, 1947.

approach but also some simple principles of anatomy and physiology. These do not, of course, compete with the aesthetic point of view, but supplement it, because surely a thing purposely designed to fit the healthy human body is no less beautiful than one which does not do so. If, for example, a machine is needed, it is necessary to make it fit the sizes of the range of men or women working it. It must be the right width and height, and attention must be given to the method of control, the handles must be so placed that smooth direction can be obtained, and they must turn in the most natural way so as not to be too easy or too stiff. Thus, examples of the type of questions which arise are: Is it better to have a push-pull lever or a turning handle? and, How must the controls themselves be shaped so that they do not rub the hands and cause breaches in the skin surface which may afterwards become infected? If the machine has indicators to tell the man or woman working it whether it is on or off, whether it is going too fast or slow or in what direction, then these too must be designed and placed for easy reading, and this at once raises the whole problem of the best way to display a piece of information to the human being. Many points here come to mind. What information is it necessary to display at all? Is it better to combine a system giving information both to eyes and to ears? Should the display be round like a clock face, or should it go up and down or from side to side? Is it better to use coloured lights, remembering that about 8% of men cannot distinguish red from green by colour alone, and that therefore indicator lights must have another clue, perhaps in their position or their spacing?

One of the great problems of interest in this whole field of the relationship of functional physiology to industrial design is how to plan and perfect experiments to give objective methods of assessment, and how to use the human being experimentally as a yardstick against which to measure the machine.

Service experience during the war was in advance of present civilian practice on this subject, and machines, like aircraft, were designed by a number of small committees composed of engineers, manufacturers, pilots, anatomists and physiologists, so that at least an attempt was made to fit machine and man together. It may be thought at first that this method may be cumbersome and slow, but it is surely clear that if it was efficient enough to work in a war of such rapid evolution as the last it is efficient enough to serve civilian uses now.

The results of this type of work in the department, all of which is fairly long-term, with the year as a unit of time, will of course be made generally available to all concerned, and I should like to feel that it will represent the joint co-operation of employer, working man, and college—in short, of Tyneside as a whole.

In addition to the interesting problems already mentioned it is important to think of health, or lack of it, as a personal and individual state to be studied at the bedside in that relationship between doctor and patient which still contains all that is best in medicine, for when a sick person comes to see a doctor, what he wants is help, and not a learned statistical analysis of his condition. It follows, therefore, that one of the fundamental difficulties to be faced in a department of this sort is how to combine the coldly critical scientific outlook of the laboratory with warm humanitarianism at the patient's bedside.

The Social Aspect

In the present way of practice in a hospital there tend to be two big gaps in our information which cannot adequately be filled by merely questioning the patient, and

they can perhaps be indicated here by asking: What social influences have been acting on him in the past before he came, and what is going to happen to him when he leaves? In other words, we usually have little detailed knowledge about his home or job, or about his progress on return. To provide this knowledge, a special type of visitor is needed, based upon the hospital and operating as a member of a team from a self-contained unit which has male and female patients, medical, nursing, and social staff all in one small area and under unified control.

The duties of this visitor or social worker will be to bring information about the patient's home surroundings and economic background, and, if possible, about his industrial environment as well, and to follow him up on his recovery and return to work. But it may be that we must have a visiting team of two—one for the home and the other for the job.

There are a number of possible trainings which fit a woman for this job of social visiting—those of almoner, psychiatric social worker, or health visitor come at once to mind—but the ideal perhaps would be an almoner with a factory inspector's training in addition. Here personality precedes training in importance, and it is essential that she should work as a member of a team and consider the social information gained objectively under a number of defined headings. There is a tendency for some types of this work to become wordy, diffuse, and sentimental, it is proposed, therefore, that the worker in this outlined department shall spend part of her time upon a specific problem which will provide as a basis something concrete and scientifically planned.

Indeed, the time is now passing when the social work of a large hospital can be adequately performed by an autonomous department functioning without a well marked chain of responsibility, either to the patient or to the patient's doctor. Moreover, this type of work at its best is time consuming and personal to the patient or his relatives, surely the social worker should undertake it in direct co-operation with the physician or surgeon who is in charge, and she should act as a full liaison officer between the patient's hospital and home, and in addition should take her share in teaching.

Some of the patients will be suffering from industrial disease within the narrow meaning of the term, which will demonstrate the effect of job on health, but a small proportion will have general medical illnesses, thus linking our specialty closely to the main subject—medicine—and, at the same time, allowing us to study the relationship between returning health and the job.

The Ward as a Co-ordinating Point

The ward, then, will be the co-ordinating point where information from the patient's home and from his work is welded on to the impression gained by the usual bedside methods. This synthesis may well take the form of a small conference attended by representatives of the four groups of people having contact with the patient—the medical, nursing, and social staff and students—because each will have something to add and, in exchange, something to learn.

When, therefore, the patient arrives in hospital he/she will be examined by the doctor in the usual way, but in addition permission will be sought by the social visitor to go to the home, and also to the patient's job, information from both these will be added to his notes, which will also contain a statement on the progress made after he/she is left with special reference to such things as how long

takes to return to his full job, and whether he maintains it or changes to another. In this way it is hoped to link together the technical excellence of the teaching hospital with the social slant of the family physician and with the industrial slant which only the factory doctor on the spot usually can have, and so to permit the passing of knowledge from one medical compartment to another. This means three diagnoses—home, job, and patient—instead of one, together with a follow-up, in one set of patients' notes.

There will also be an out-patient department, working closely in conjunction with the ward, where people will be seen who are not ill enough to be in bed, and where they and their doctors can be advised about their illnesses. It is most important that a department which spends the greater part of its time upon research should keep its feet firmly on the ground of everyday medicine, and it should therefore share, even if only to a small extent, the hospital's daily work.

From time to time students and assistant doctors will accompany the social worker on visits to gain first-hand knowledge of home and working life, because it is clearly illogical that the first time that a medical student sees a patient in his own home (with the exception of a brief training in midwifery) is as a general practitioner after he is qualified, and the same is true of seeing the patient at his work, which he may never do unless he becomes an industrial doctor. It must never be forgotten that a man is the same man whether at his work or in his home, and, ideally, the same doctor should know about both parts of his life. It is important, moreover, that a university department such as this should attempt to practise and to preach that which is biologically true rather than that which seems at the moment to be administratively expedient, and that it should also try to do something to offset the increasing compartmentation which is spreading so quickly through medicine as a subject.

This conception is, of course, entirely experimental, and there are clearly a number of potentially weak points which will need watching. For example, the proportion of time spent travelling to homes and factories may prove too great, patients or their wives may resent a visitor intruding into houses already somewhat over-visited, and the same may happen at the places where they work, but these are only stimulating difficulties to be overcome with tact and the right approach.

The New Department and the Student

The laboratory in the new department will be used as a tool in the investigation of the more intricate and the more fundamental relationship between man and machine, and here also will be studied those problems in mechanical design already mentioned. This has a practical as well as an academic interest, because it is directed towards better mechanical control, less fatigue, and fewer accidents.

Now health, like charity, should begin at home, and in the future it may well be that the college student's health becomes the responsibility of this department. But care must be taken to distinguish between the detection of a disease and its prevention. One of the most important functions of any students' doctor will be to act as health adviser to the college. He must consider it as an industrial organization, have a good knowledge of the physical and psychological conditions of each faculty, and thus know something about the educational and other loads which press upon the various groups of men and women. He will then in time be able to advise upon such things. On the whole, good organization of work, play, food, and lodgings will prevent more disease than detective methods working relatively late, routine medical examination must of course

be done only after it has been decided to admit the student, and the dulling effect upon the doctor of examining large numbers of normal young people must be considered. We know little about the liability of young men and women to disease, or how they spend their money or their time, and surely there is here an opportunity to combine both prevention and research.

You will no doubt have noticed that, apart from a few passing references little has yet been said about teaching, and this is because from our departmental terms of reference it must stand second to research. Nowadays the layman rightly expects the doctor to have a wide intellectual horizon and more knowledge of the cause and prevention of disease, and a better appreciation of what is common and important and of what is uncommon and unimportant, however technically interesting the uncommon state may be, yet it may well be doubted in this case whether the customer really is getting what he needs. Mental flexibility is not encouraged by an overcrowded course which teaches too many facts that are of little use, and which does not stress enough the scientific method of their collection, and still less their orderly arrangement and rearrangement in logical argument. Reflective thought flourishes only when there is leisure and free informal discussion among small groups of people—and the medical student is at present allowed too little of either. Indeed, sooner or later the present method must be left behind wherever students are given a course in what is really gross clinical pathology of the museum type and then an attempt is made to undo the wrong with some sort of postgraduate technical diploma. The aim should be to produce the type of mind which can design a way of life instead of merely prescribing physic, which knows something about what is inside and what is outside the normal environmental range, and which thinks in terms of prevention rather than of so-called cure. Industrial health is not a specialty within the usual meaning of the term but is a reorientation of the general subject, and it is highly doubtful whether in the future it will be wise to organize it as a narrow-minded special service. After all most places of employment are small and could, and should, be looked after by the general practitioners in the area, with advantage both to doctor and to patient since the doctor will have a wider type of interest and the patient will be cared for by a man who has a better chance of knowing both his job and his home.

How, then, in the light of these considerations should industrial health be taught? It is surely clear that it may perhaps one day replace in the general medical course some dead wood which must be cut away, and that it must not be made an additional subject to be loaded on the already groaning student. A game is learned best by those who play it, and it is proposed, therefore, that students should be allowed to co-operate in the experimental work, when they will learn something about the scientific method and about the application of physiological principles to practical problems. Again, visits to workplaces and home should rank as part of the usual course in medicine, and it may well be that it should be compulsory for every student to attend a number of the small case conferences and clinical discussions already mentioned so that he can see an attempt being made to print the whole picture of a patient's health. The formal lecture will not rank high in our teaching plans, because in a course like this the need is not for facts but for food for thought, and this is best imparted informally to the smallest number possible. Much of the teaching of this subject will be oblique, using visual methods of display by photographs and other changing demonstrations. For example, there

may well be staged, in some convenient place, a selection of protective industrial clothing. A miner, after all, wears a hat, a lamp, and sometimes knee-pads, but few students know exactly why, and still less do they realize that these represent elementary steps in preventive medicine.

Staffing the Department

I have dealt to some extent with what this department has to do, and now can outline briefly the staff needed to undertake the task. In the early stages of the bedside work full clinical responsibility should be borne by the departmental head, but later, as the work increases and plans mature, a competent clinician capable, if necessary, of bearing the full load must be employed. He should, moreover, have another interest in some investigation of his own. Under him would come two junior assistants, spending part of their time on clinical work and part on fundamental research, and part again in helping with the routine departmental teaching. These men or women will be at the stage of deciding whether, or how, they intend to advance themselves, and, if so, in which of the branches of activity displayed before them in the department, and one of them will join the social worker as a small combined team of two. Finally will come a house-physician of some previous medical experience who may one day become an assistant in his turn.

On the laboratory side it is most necessary to have a man who combines a knowledge of statistics with a social or biological outlook and who will perhaps in time develop a small subdepartment of his own, there are needed, too, a physicist or engineer who can plan and make machinery to study our problems of design, and a non-medical but biological assistant to use this machinery as a tool to answer the questions posed. Occasionally, but very rarely, one man can do both of these, but usually the purer type of scientist has difficulty in dealing with the variability of response of human beings, and, vice versa, few biologists have the necessary technical knowledge to design the apparatus used. Finally there must be, of course, ample help in computation and secretarial work, because otherwise much time will be wasted.

The "foreign policy" of a department such as this should be to maintain the closest contact with both employer and employed, to eschew politics and compensation questions like the plague, and to avoid the role of expert witness. It should, moreover, work in close connexion with the local department of public health, and with the sister—perhaps one should say the elder sister—Nuffield Department of Child Health.

Conclusion

To summarize the story, it can perhaps be said that an organization such as this should have five main duties: (1) to its patients, which it must treat as persons as well as members of an industrial or social group, (2) to its subject which it may advance a little, chiefly by affording a seed-bed for the germination of potential workers in this field, (3) to the students, by reorientating their medical horizon, (4) to its college, by concentrating mostly upon research, and only slightly upon teaching, and (5) to employer and employed by maintaining a tactful, fair, and independent attitude in its outside work.

May I now conclude with some words of John Dryden's which do, I think, foreshadow this new spirit in preventive medicine?

Better to hunt in fields for health unbought,
Than fee the doctor for a nauseous draught,
The wise for cure, on exercise depend,
God never made his work for man to mend

SURGICAL EMPHYSEMA DUE TO COMPRESSED AIR

BY

A. M. DESMOND, F.R.C.S.

In the last twenty years compressed air has been employed in industry on an increasing scale, and the hazards associated with its careless use are now well recognized. Emphasis has been placed particularly on injuries of the rectum and colon, and Wyllys Andrews (1911) and others have given excellent surveys of this aspect of the subject. One feels, however, that the occurrence of tissue emphysema in the presence of even the smallest wounds has not been sufficiently brought to notice, and for this reason the following case is considered worth recording.

Case Report

A metal miller aged 16 years was working on the "mille, and a small piece of metal shaving (referred to in the trade as 'swarf') punctured the ulnar side of the palm of his left hand about 1 in. (2.5 cm) proximally to the base of the little finger. He removed it, and the minute pin point wound bled a little. He then, in an attempt to remove the remainder of the 'swarf', directed the nozzle of a powerful air compressor pump on to his hand, which instantaneously became ballooned and painful. He was examined within two hours, and complained only of the swelling and pain.

The ulnar side of the palm was diffusely swollen and tender, the swelling roughly conforming to the size and shape of the palmar space, with ballooning of the webs between index, middle, ring, and little fingers (see Fig.). The palmar creases

Showing the ballooning of the palmar tissues. The puncture wound is indicated by arrows.

over the area involved were almost obliterated. No crepitus was elicited. The remainder of the hand, the fingers, and the forearm were normal, there was no swelling of the dorsum. There was a pin point puncture wound in the position described above and scattered over the surface of the hand were multiple cuticular abrasions. An x-ray photograph showed air in the

oft tissues of the ulnar side of the hand and of the webs between the fingers, but none on the thenar side. The emphysema thus appeared to be confined mainly to the palmar space and its lumbrical extensions.

He was treated by local heat, sling immobilization, and a prophylactic course of sulphadiazine, 1 g by mouth every four hours. Next day the hand remained swollen but was less painful. There were slight pyrexia (99°F , 37.2°C) and some redness around the puncture wound. Sulphadiazine and immobilization were therefore continued. The following day the swelling had completely subsided, there was full function and no pain. A further x-ray examination showed a normal soft tissue shadow, and he returned to work six days after the accident.

Discussion

The air compressor responsible for this accident is one used for blowing the metal filings and chips away from the metal being cut, so that the field of work is not obscured. It is similar to the familiar automatic pump used in garages for inflating tyres, and pumps air at a pressure of 75-90 lb per sq in (5-6 kg per sq cm). When directed on to the unabraded skin it causes no discomfort but is sufficient to make a deep indentation in the tissues. Whitwell (1944) published a somewhat similar case, in which subcutaneous emphysema occurred in the middle finger from an identical cause, but he was able to elicit the typical crepitus of surgical emphysema. In his case the condition subsided without sepsis. Another use of compressed air is as a method of cooling when using a lathe, etc. A third, and more extensive, use is in compressed-air tools such as pneumatic drills, riveters, etc. Parker (1937) records a case of extensive emphysema of the whole hand in which a workman, having a deep wound, accidentally pressed his palm over the exhaust opening of a pneumatic drill. In this case, too, the emphysema subsided without complications.

The present case is of interest for two reasons. First, in spite of the extremely small wound, a large quantity of air penetrated even to the deep subfascial tissues, secondly, the extraordinary manner in which the air inflated the palmar space. It will be remembered that this space is bounded by the intermediate palmar septum laterally, and that this septum lies between the flexor tendons of the index finger and the second lumbrical muscle. The skiagram showed that the air in the tissues reached exactly to this point and did not encroach on the thenar space. It will also be remembered that the palmar space communicates distally with the subcutaneous tissues at the webs between the fingers along the lumbrical muscles. The air was well shown in these extensions in the x-ray picture. The palmar boundary of the space is the dense palmar fascia and the common flexor synovial sheath. This adequately explains why crepitus was not elicited. The dorsal confines of the space are the third, fourth, and fifth metacarpal bones, the fascia covering the interosseous muscles of the third and fourth spaces, and the fascia covering the medial part of the transverse head of the adductor pollicis. These would prevent extension of air into the dorsum of the hand. Medially the boundary of the space is the medial palmar septum, lying close to the lateral side of the opponens minimi digiti and passing deeply to be attached to the anterior surface of the fifth metacarpal bone. The septum extends distally to become continuous with the fibrous tendon sheath of the little finger on its ulnar side. Proximally it reaches the hook of the hamate and the pisohamate ligament and is pierced by the deep branches of the ulnar nerve and artery. This may possibly explain the presence of air in the subcutaneous tissues around the ulnar styloid process and in the subcutaneous tissues on the medial aspect of the base of the little finger in the x-ray. However, there appeared to be some more superficial air in the hypo-

thenar region, and it is probable that it penetrated the subcutaneous tissues here before the larger quantity entered the palmar space.

These accidents are well known in industrial medicine, and no record of any untoward results could be found in the literature. However, should infection occur, it is conceivable, if not probable, that the consequences might be more serious to the patient. Whether the accident could occur in an already infected wound, walled off by tissue reaction, it is impossible to say, but, if so, a spread of infection would be practically inevitable. It would appear to be of utmost importance that the condition be recognized early and prophylactic treatment undertaken. Furthermore, the workmen should be warned of the possibility of the occurrence. Not one workman at the small metal milling factory at which this incident occurred was aware of these dangers.

DIGITAL FOREIGN BODIES IN SPOT-WELDERS

BY

W. A. B. REYNARD, M.B., Ch.B.

Principal Medical Officer Pressed Steel Co. Ltd
Cowley, Oxford

AND

FREDERICK SMITH, M.B., Ch.B., F.R.C.S. Ed.

Assistant, Accident Service Radcliffe Infirmary, Oxford

Of the countless varieties of injuries sustained by the human body in this industrial age the hand receives perhaps more than its fair share. An unusual type of lesion has come to our notice lately. This is an industrial injury to the hand and fingers sustained by those engaged on the job of spot welding.

Resistance welding, or spot welding as it is more popularly called, is a process by which two or more pieces of metal are joined together by a combination of mechanical pressure and the heat which is generated in the metal by the passage of an electric current. The pieces to be welded are held under pressure between two copper electrodes and a current is caused to flow. As an example of this, when spot-welding two thicknesses of mild steel sheet each 0.04 in (1 mm)

Fig 1—Girl using spot welding machine showing the use of the right hand to position the part to be welded and how this brings her fingers in close proximity to the electrodes whence the sparks emanate.

FIG 2—Man using spot-welding gun, showing that his hands are well away from the electrodes

thick the welding conditions are diameter of tip surface of electrodes, 0.25 in (0.63 cm), welding pressure on electrode-tip surface, 10,000 lb/sq in (700 kg/sq cm), welding current, 8,000 amperes, voltage across the electrodes, less than 1 volt, welding time 0.2 second

In practice, spot-welding is applied either by means of a stationary "machine" (Fig 1) or by means of a mobile "gun" (Fig 2). The machine is used when small objects are being welded, and the gun is used on a large job. When using the machine the small object is held between the electrodes by hand, a pedal switch is depressed, and this causes the electrodes to approximate and squeeze the metal parts together and the current to flow. In the case of the gun, which is portable, when its electrodes are brought into position one hand is used to steady it, the other to switch on the current, thus both hands are necessarily far away from the area to be welded. In each type, as the current is flowing and the weld is being made, there may be a spraying outwards of sparks of red-hot metallic particles. For the most part this "splashing" of sparks is absent or negligible in amount, but in some instances, for a variety of reasons, a much heavier "splash" occurs.

This discharge of sparks can be seen wherever spot-welding is being done. They collide with various parts of the worker and his clothing, but it is the common finding of industrial medical officers that on the whole they do little or no damage. A spot-welding operator usually shows evidences of his occupation by the presence of minute superficial burns of his hands and arms caused by contact

with the flying red-hot particles, but these burns are regarded as a trivial and transitory annoyance and of no disability. Occasionally injury to the eye occurs that is outside the scope of the present article.

Six months ago we noticed in the factory a case (Case 1) in which the sparks had penetrated the fingers of a worker and since that time we have been on the look out for such cases. Eleven more have presented themselves. The cases have all occurred in the factory in which one of us (W. A. B. R.) is medical officer, and have all been referred for surgical treatment to this unit.

Reports of 12 Cases

Case 1—C. M., a female spot-welder aged 18. While spot-welding small steel brackets on Nov. 13, 1945, she received a jet of sparks from the welding machine into the tip of her right forefinger. She felt a stabbing pain and rapidly the finger became white at the tip, painful, and began to swell. The wound of entry was so minute as to be almost invisible. The event. The pulp felt and looked hard. On Nov. 20 she reported the injury at the works hospital. Treatment instituted, and kaolin poultices were applied daily for a week. At the end of that time a small metallic foreign body was picked out with an eye-spud, and temporarily the finger settled. On Jan. 1, 1946, the finger became painful again. Another piece of metal was removed and a small abscess evacuated. By Feb. 25 the acute pain, swelling, and tenderness had subsided, but she complained of a pricking sensation in the finger when handling small objects and tenderness to the slightest touch. Her disability had necessitated a change of job to one in which fine finger movements were not essential.

On examination a very hard tender scar at the finger tip had resulted from the injury and the sepsis that followed. There was no acute inflammation and no axillary adenitis. The finger and hand were mobile and otherwise normal. A skiagram showed multiple MFBs lying in the pulp of the digit parallel to the terminal phalanx. No evidence of bone injury or disease was seen. **Surgical Treatment**—On March 11 a lateral incision was made, extending into the cornified entry wound at the finger-tip, and a minute superficial cavity containing necrotic material was opened up. There was no frank pus. Deep to this cavity the MFBs were located and as many as possible extracted by the point of the knife. The wound healed by first intention, and when seen again recently the patient had no complaint. She had returned to her old job of spot-welding on April 8.

Case 2—T. C., a male spot welder aged 42 while welding on Jan. 26, 1946, received a spray of sparks from the machine into the dorsum of the terminal phalanx of his right middle finger. It quickly became swollen and painful. He went to the works hospital and was treated by a sterile dressing and later, kaolin poultices. During the next two months several pieces of metal were extracted on two occasions from suppurating sinuses at the site of injury. On March 19 he complained of tenderness and a throbbing pain in the finger. On examination a hard, blackened, and calloused spot was seen at the wound of entry on the dorsum of the terminal phalanx. The middle finger and a similar lesion was noted on the dorsum of the ring-finger. Both areas were tender to pressure. There was no acute inflammation noted, no lymphangitis or axillary adenitis. He thought the ring-finger lesion had occurred in January, but he wasn't sure, and it did not give him a skiagram showed multiple MFBs in ring and middle fingers, but no evidence of bone injury or disease. **Treatment**—By March 25, when he attended for surgical treatment a small spot of pus was visible at the entry wound on the middle finger and the axillary glands were enlarged and tender. The superficial abscess on the middle finger was incised and two pieces of metal which lay loose in the cavity were removed and the incision left open for drainage. From the ring finger numerous small MFBs were extracted and primary suture was carried out. By April 9 both wounds were well healed and painless and he had resumed work as a spot welder.

Case 3—W. K., a male spot-welder aged 39. On Nov. 1, 1945, while spot-welding, a jet of sparks entered the pulp

the left little finger and the dorsal surface of the terminal phalanx of the right ring-finger. Both wounds were fomented daily, and a week later pieces of metal were picked out with a needle from each wound. The little finger healed quickly thereafter, but the ring-finger discharged pus for ten days before healing. When seen in March, 1946, he complained only of a tickling sensation on pressure. There was no evidence of infection. A skiagram showed a spray of MFBs in each of the affected fingers. As the patient considered his symptoms to be trivial he was not keen to submit to operation, and nothing further was done. He has continued to work as a spot welder and is without disability.

Case 4—A M., a male welding charge hand aged 36, on April 22, 1946, sustained a jet of sparks into the pulp of the terminal phalanx of the right index finger. Immediately it became very painful and swollen, and remained so for a few days, after which the condition settled down without treatment and without complications. After a week the small entry wound became hard and cornified. The resultant scar wasumpy and tender to pressure. There was no throbbing or pain. May 29 the finger had become inflamed, swollen, and painful. At the site of injury there was a small black cornified spot with a surrounding yellow area and a slight sero-purulent exudation. A skiagram showed multiple MFBs but no bone involvement. **Treatment**—A lateral incision was made on May 31 and inspissated pus was evacuated from the superficial aspect of the wound and most of the MFBs extracted with the aid of an electro magnet. The wound was left unsutured. A post-operative skiagram showed that most of the MFBs had been extracted. The wound healed quickly and well. He was still working in his pre accident job.

Case 5—A T., a male spot-welder aged 52. While spot-welding on May 30, 1946, he received a spurt of sparks from a machine into the pulp of his left index finger. He was seen within two hours of the accident. At the site of injury there was the erythema of a thermal burn with a few small black spots in its centre. A few hours later the finger became swollen and gave much pain overnight. Next day a small blister appeared at the wound site. A skiagram showed multiple MFBs but no bone or joint involvement. A lateral incision was made and the pus drained from the blister, the main mass of underlying MFBs extracted, and the wound left unsutured. A post operative skiagram showed that only a few dust like particles remained. He resumed work as a spot-welder two days later, and was without disability on Sept 10.

Case 6—G S, a male spot-welder aged 25. On Aug 13, 1946, he was welding parts of a motor chassis, using the spot-welding machine, when sparks penetrated his right thumb. He felt a sharp stab of pain, the site of the wound went white, and after a few hours the thumb was quite swollen. He did not

FIG 4—Enlargement of the thumb of Case 6 showing the wound of entry

attend the works hospital until next day. For three weeks the wound periodically healed and broke down again, with discharge of pus and metallic particles. The interphalangeal joint became progressively stiff and painful on movement. On examination on Sept 3 there was a small hard lump consisting of a central black spot with a white halo and a peripheral area of erythema on the lateral aspect of the right thumb opposite the interphalangeal joint. In addition the marks of his trade were very apparent. There were two black spots on the flexor aspects of his right index and little fingers (Figs 3 and 4).

On the front of the wrist were fresh superficial burns, minute scars of old burns, and abrasions and linear scratches due to flying particles of steel. He had been welding steel sheets of

extra thickness, and although his hands were relatively far away from the electrodes the spark output was heavier. Skiagrams (Figs 5 and 6) showed numerous opaque foreign bodies close to but not in the interphalangeal joint. Flexion of the joint was limited to half its normal range. By means of an electro-magnet most of the metallic particles were extracted and the wound was left open for drainage. He resumed work as a spot welder on Sept 16, and on Nov 12 was without disability.

Case 7—E P., a male assembler and temporary spot welder aged 38, received a spurt of sparks from the spot-welding machine into his left index finger on Aug 13, 1946. He said the injury almost paralysed the finger. It was very painful and began to swell soon

FIG 3—Photograph of the hand of Case 6 showing a number of the relatively unimportant superficial burns commonly sustained by spot-welders. Also seen on the thumb is the wound of entry of MFBs.

FIG 5—Case 6 Skiagram showing the digital lesion

FIG 6—Skiagram of Case 6 taken after operation

afterwards. He reported to the works hospital two days after the event and kaolin poultices were applied. The wound healed quickly, but thereafter broke down every few days with discharge of pus. On examination on Sept 13 a typical lesion was seen on the flexor aspect of the middle of the terminal phalanx of the left index finger. It was tender to pressure and dry. There was no joint or tendon involvement. A skiagram showed MFBs in the pulp of the left index finger, but no bone or joint lesion. The metallic particles were excised, and he resumed work as a spot welder on Sept 13, when seen on Nov 12 he had no disability.

Case 8—R S, a male, aged 56, while spot welding small brackets on a machine on Aug 27, 1946, and wearing cotton gloves, sustained a jet of sparks into the pulp of the left thumb. Inflammation, swelling, and pain resulted, and kaolin poultices were applied daily. On Sept 3 two pieces of steel were removed from a pin head abscess at the site of injury by probing only and without incision. On the 12th a dark, rough, cornified area appeared at the site of entry. There was no inflammation or oedema. Slight pricking on pressure was the only symptom and this gave so little trouble that surgical intervention was unnecessary.

Case 9—E I, a female spot-welder aged 23. On Sept 2, 1946, while welding small brackets on the spot-welding machine a splash of sparks entered her left index finger. No pain was felt at first, but some hours later the finger began to swell and throb. She reported for treatment next day. Kaolin poultices gave ease, but the wound discharged moisture for ten days before it healed. Examination on Sept 13 showed a lesion situated on the flexor aspect of the left index finger over the distal interphalangeal crease. It was dry and tender to pressure. Joint movements were of full range, without tendon involvement. A skiagram showed MFBs situated in soft tissue of the middle flexor aspect of the middle phalanx. No bone or joint was involved. The foreign bodies were excised, and next day she resumed work as a spot welder. When seen on Nov 12 she was without disability.

Case 10—W E, a male jig hand aged 27, sustained a splash of sparks into the lateral aspect of the terminal phalanx of the left ring finger while spot-welding on Aug 23, 1946. An x-ray film disclosed numerous MFBs, but no bone lesion. The affected area was inflamed and tender and in the centre was a minute dark entry wound. An occlusive dressing was applied. On Aug 30 there was still some inflammation but no pus and no oedema. On Sept. 9 the only disability was very slight pricking on pressure, but this is not often felt, as the lesion is situated laterally. Surgical intervention was not required.

Case 11—A P, a male aged 35, was using the spot welding machine on Sept 13, 1946, when sparks penetrated his left thumb, he reported this fact soon afterwards to the works hospital. Apart from the initial stab of pain the lesion did not cause discomfort, but the immediate vicinity of the entry wound became blanched and tense. At the radial side of the base of the left thumb there was a small collapsed blister with a surrounding area of erythema. At the centre could be seen a hard black core from which exuded a pin-point of serum on pressure. A skiagram showed the presence of multiple MFBs close to but not actually in the first metacarpo-phalangeal joint. Surgical treatment was carried out within six hours. The area of the lesion was completely excised and primary suture performed. Healing was by first intention, and he returned to his job on Sept 23. When seen on Nov 12 there was no disability.

Case 12—N S, a male spot-welder aged 35. On July 20 1946 a splash of sparks from the machine penetrated his right index finger. He felt a burning sensation at the time of injury and had little discomfort afterwards. About four days later the finger began to throb and swell. He first came for treatment on Sept 27, when the findings were as follows. Right index finger raised pus-filled blister on the radial aspect of the interphalangeal joint. Joint movements were limited owing to inflammatory oedema surrounding the lesion. An x-ray film showed multiple metallic foreign bodies. The MFBs were removed by excision the same day and the opening was drained. The patient resumed work as a spot welder on Oct 5, and when seen on Nov 12 was without disability.

Comment on the Cases

From the foregoing it will be seen that the lesion consists of a superficial burn, minute entrance wounds, and underlying foreign bodies. The red-hot sparks are sterile, but dirt and bacteria may be carried in from the skin surface. In addition the heat coagulates and devitalizes an area surrounding the particles, thus producing a field particularly prone to the onset of infection. The symptoms are primarily those of a burn and, later, those of retained foreign bodies with chronic inflammation. In our cases the metallic particles had lodged in the pulp and cellular tissues of the fingers, but if the more specialized anatomical structures—joint, nerve, tendon, bone—should be involved, a more serious outcome might be expected. Even in the form described above, in which the finger-pulp is affected, involvement of nerve fibrils in the finger-tips can lead to much tenderness and disability. These workers depend for their livelihood upon the exact and full function of their fingers, and if to pick up an object causes severe pricking pain they are seriously handicapped.

Treatment

First Aid—This calls for a sterile occlusive dressing, a sling, the injection of antitetanus serum, and a sedative for the relief of pain. Preparation should then be made for the patient to receive surgical treatment.

Early Surgical Treatment—If seen within eight to twelve hours of injury the procedure indicated is wound toilet, excision of dead tissue, extraction of metallic particles, and primary suture. The operation is carried out with all the usual theatre facilities. Either regional "novocain" block of the digital nerves or general anaesthesia is satisfactory, and a bloodless field is obtained by means of a rubber catheter tied round the proximal end of the finger. Incisions are placed laterally and enclose the wound of entry if possible. If the lesion is more centrally situated the incision is still made laterally and the entry wound excised separately. Although most of the metallic particles can be seen and removed by the point of the knife the procedure is facilitated by the use of an electro-magnet: the foreign bodies are magnetic, and even dust-like particles can be withdrawn. The operation is completed by the insufflation of penicillin powder and primary suture.

Late Surgical Treatment—Cases which arrive for treatment later than twelve hours require immediate surgery only if infection is present. Even if no infection occurs, tenderness, irritation, lumpiness, or loss of fine sensation may be present, and these are indications for removal of the metallic foreign bodies. In certain cases, even in the absence of symptoms, excision is indicated, as the presence in the tissues of multiple MFBs remains a source of danger. Chronic suppurative and sinus formation necessitate incision and drainage, with removal of the causative foreign bodies.

Prevention

It will be noted that all the above cases occurred in workers engaged in the use of a spot-welding "machine" as opposed to a "gun". The reason for this is that the process of welding small parts on a machine may entail the positioning of the part with the fingers close to the electrode as the weld is being made: the fingers are therefore exposed to the splash of sparks close to their origin and at their point of maximum velocity. In the case of a gun operator, on the other hand, the hands are both employed in holding the gun and operating the switch, and are therefore out of harm's way.

There are many technical causes of an increase in the amount of sparking produced in the process of welding.

JUNE 14, 1947

Among these may be included foreign matter on the surface of the metal, inaccurate placing of the weld on the edge of the sheet of metal, maladjustment of the machine, etc. But even under ideal conditions sparking will occur in a certain number of cases. Such being the case, the problem of prevention is to devise a means of protecting the hands of the worker from these sparks. This might be achieved by one of three methods

(a) By applying to the machine a guard which would protect the operator's hands or prevent them from being brought close enough to the welding point to be in danger. This would be the ideal method—being permanent and foolproof, and in no way demanding the co-operation of the worker. Unfortunately, no such guard yet conceived will permit of the welding machine being used

(b) By the use of a jig for positioning the parts to be welded and thus removing the necessity for the operator's fingers to be close to the welding point. This is possible in many cases, but in some is technically impracticable. Also, in practice there is the very real danger that the operator will place ease before safety and discontinue the use of the jig

(c) By the provision of tongs or protective gloves. This is analogous to the provision of goggles for the protection of the eyes, and possesses the same disadvantages—namely, that through laziness or carelessness on the part of individual operators they will be temporarily or permanently left off. As is well known by all industrial medical officers, protective clothing can easily be devised and provided, but it is most difficult to persuade operators constantly to use it

It has been found that neither industrial cotton nor leather gloves afford sufficient protection, and we have experimented with various other materials. Those most satisfactory to date are cotton gloves coated with "neoprene" and asbestos fabric finger-stalls worn under the usual cotton gloves. We now have both of these in use but are continuing our search for the ideal material

We are grateful to Mr J. C. Scott, Director of the Accident Service, Radcliffe Infirmary, for his help and encouragement in preparing this paper, and would like also to acknowledge the assistance given to us by the welding and laboratory staff of the Pressed Steel Company

SYMMETRICAL GANGRENE IN THE AFRICAN

BY

MICHAEL GELFAND, MB, MRCP, DMR
Government Medical Officer Salisbury Native Hospital
Southern Rhodesia

Gangrene in the extremities can generally be attributed to diabetes, arteriosclerosis, or thrombo-angitis obliterans. Ergot poisoning is a relatively rare cause. Arteritis resulting in gangrene is described in acute infections, such as typhus and typhoid fevers and malaria. Gangrene has been noted in pellagra or the vitamin B deficiency state (Page, 1946). It is also seen in those cases where the arteries are suddenly occluded by an embolus, subacute infective endocarditis being a typical instance. Occasionally in Raynaud's phenomenon, there are trophic changes in the tips of the fingers. Traumatic cases, forming a separate group, are also seen. Trench foot and the immersion-foot syndrome following exposure to cold constitute another class of cases in which gangrene of varying extent is the most important feature

I have encountered gangrene in an extremity in the elderly African, presumably due to arteriosclerosis, and unilateral gangrene, which might have been attributed to syphilis. There appears to be very little written on Buerger's disease in the African. I have not encountered a case in the native. Ferro-Luzzi (1942) reports on 20

cases of Buerger's disease in European males living in Eritrea, but he failed to find the condition among the indigenous population. Goetz (personal communication), however, has seen a case in the African

During the past four years I have seen six cases of symmetrical gangrene in the African, running a peculiar but nevertheless more or less constant course. In each the course and history were similar. (1) The onset occurred in a person who previously enjoyed more or less good health. (2) The disease was seen only in males. (3) It occurred usually between the ages of 20 and 35—one patient, however, was over 50. (4) The first sign was oedema of both feet, this was followed by pain. (5) The gangrene occurred simultaneously on each side. (6) No obvious cause common to each case could be found for the disease

In four cases the gangrene was limited to the tips and pads of all the digits. In one the gangrene ascended to the mid-tarsal joints, being exactly symmetrical on both sides. In the sixth case the whole of both feet and up to 3 in (7.6 cm) above the ankle-joint on each leg was affected

All the cases came from Mashonaland, but from widely separated regions. They were seen at different periods over the four years. In none was there anything to suggest that other cases with gangrene had occurred in the villages from where they originated. The patients denied having received any treatment from a witch-doctor or of having consumed any native drugs prior to the onset of the disease. They all stated that they had previously been well. In two of the six cases the Wassermann reaction was positive. In one of them the disease was immediately preceded by cerebral malaria, but in no other case was acute malaria found. No sugar was found in the urine of any of the patients. The blood pressure was normal in each. The clinical features of the two cases in which extensive gangrene occurred were as follows

Case 1

An African man aged about 30 first became ill on June 11, 1945, with general malaise and shivering. He vomited twice on the first day of the illness. During the night he developed severe headache and passed into coma. He was admitted to the Salisbury Native Hospital from Norton (about 25 miles away) on June 14. The coma continued for two days, after which he gradually regained consciousness (June 15).

On admission the blood smears were positive for *Plasmodium falciparum* and quinine was given by injection 10 gr (0.65 g) twice daily for two days. The cerebrospinal fluid was clear. There was nothing abnormal in his legs. On June 16 the day after his recovery from the comatose state and acute malarial condition, the patient first complained that his legs were heavy to lift. It was noticed that his feet, ankles and the distal halves of his legs were swollen and showed pitting oedema, but there was no pain. A day or two later his legs and feet were very painful to touch. Several days later it was noticed that the skin of both feet was hard and cold up to 3 in (7.6 cm) above each ankle-joint. The feet were discoloured black, this being most clearly seen on the soles and the pads of the toes. Three distinct zones were noted on each limb. The most distal one, from the toe-tips to past the mid-tarsal joints, was pitch-black, due to total gangrene. The middle zone, which reached to about 3 in above the ankle-joints, was cold and swollen. Above this was a narrow zone, which was warm and faded gradually into the normal temperature of the leg. All the toes were affected by dry gangrene. No pulse could be felt in the anterior and posterior tibial arteries, but that in the popliteal and femoral region was easily palpated and was of equal force in each limb.

The patient was thin. There was no oedema in any part of the body until it appeared in the legs. Jaundice was not detected. The conjunctivae were pale as was the tongue. The gums were slightly spongy. There were signs of a pellagroid rash

on the hands and feet. Abdominal distension was not present, nor was the spleen or liver palpable. Nothing of note was found on examination of the central nervous system. The cardiovascular system was normal, the blood pressure being 110/80. The Wassermann reaction of the blood and cerebrospinal fluid was negative. No sugar or albumin was present in the urine. The blood count was: red cells 2 570 000 per cmm, haemoglobin, 40%, colour index 0.78, white cells, 24,500, neutrophils, 74%, lymphocytes 22%, monocytes, 4%.

Before admission to hospital the patient's diet consisted of maize and meat—quite an ordinary one for an African. Life and food were shared with other labourers in a labour camp, and the patient stated that so far as he was aware none of the other inmates of the camp had been afflicted with his complaint.

The gangrenous areas were treated with dry sterile dressings. However, after ten days moist gangrene set in, and amputation was recommended. The infection spread and the gangrenous area became swollen and offensive, but the patient could not be persuaded to consent to an amputation. He insisted on leaving hospital and was discharged on July 13. Trace of him was then lost.

Case 2

A native youth aged about 16 was admitted to the Salisbury Native Hospital on July 1, 1945, complaining of swelling and pain in both feet. He came from the Lnkeldoon District (about 100 miles away). He was quite well until two weeks previously, when he began to have lumbo-sacral backache. There was no preceding history of malaise, vomiting, headache, consumption of drugs, or eating of food other than that to which he was accustomed. He had not previously visited a witch-doctor. A week after the onset of the backache he noticed that both his feet had begun to swell. The oedema was followed by pain in the feet. The patient was quite certain that the swelling preceded the pain by two days. A week later he noticed that both feet had changed colour, becoming darker and blacker. His diet on the whole was a fairly satisfactory one, consisting of maize daily, meat four times a week, pumpkin three times a day, sweet potatoes every day, monkey-nuts occasionally, and certain wild fruits. He ate worms, caterpillars, locusts of the larger type, and white ants.

On examination he was fairly well covered with no sign of nutritional disease. The lungs were clear and the heart normal. The blood pressure was 120/60. The spleen and liver were not enlarged. The blood count was: red cells 3 750 000, haemoglobin 71%, colour index, 0.94, white cells, 11 300, neutrophils, 68%, lymphocytes 21%, monocytes, 6%, eosinophils 5%. The blood Wassermann reaction was positive.

FIG 1

There was dry gangrene of all the toes and both feet up to the tarso metatarsal joints, the affected parts being black and cold. The gangrene was symmetrical in extent (Fig 1). Immediately above the gangrenous area in each limb was a zone of demarcation, 1 in (2.5 cm) in depth, above which again was

a band of hyperaemia which gradually faded into the normal temperature of the rest of the limb. The popliteal and femoral pulsations on each side were normal and equal. The dorsalis pedis and posterior tibial arteries could be felt pulsating.

Towards the beginning of August, spontaneous amputation was noticed at the line of demarcation in the left foot, and on Aug 20 a similar line was seen in the right foot (Fig 2). Next day the left foot was amputated at the line of demarcation.

FIG 2

in the tarso metatarsal line, and on Sept 7 the same operation was performed at the corresponding site in the right foot. The sites of amputation healed soundly and the patient was otherwise perfectly fit. He became anxious to leave hospital and was discharged, and returned to his kraal.

Discussion

The oedema is difficult to explain, since it is not usually a feature of arterial obstruction alone. Oedema in vascular disorders may usually be attributed to venous or lymphatic obstruction, local infection, or perhaps to disease of the capillary walls with resulting increased permeability. An example of the last type may be seen in Buerger's disease (Saint, 1945) or in ergot poisoning. It is possible that the oedema is the primary cause, producing secondary interference with the circulation of the limb, foot, or toes. The oedema appears rapidly in these cases and is of moderate degree. It may have been due to a thiamine deficiency. Case 1 was, in fact, given thiamine, 20 mg daily, by intramuscular injection as soon as the oedema was noticed. It lasted only a few days and then disappeared, but by that time gangrene had supervened.

It will be seen that the primary cause of the admission of Case 1 to hospital was cerebral malaria, and that the limb disorder followed soon after. It would thus be reasonable to exclude ergot or other drugs which might possibly have been consumed before admission. The limb disorder may, however, be attributed to the severe malaria infection or to a spasm of the arteries in the legs following the administration of quinine.

From the above description it will at once be clear that Raynaud's disease and thrombo-angitis obliterans are easily ruled out. Raynaud's phenomenon produces discoloured lesions including small cutaneous trophic lesions with fibrosis in the fingers and toes (Saint, personal communication), but this occurs after a long interval and not, as in the cases described, after a single attack. Raynaud's disease confined to the toes is uncommon, whereas in the present cases the disorder was limited solely to the lower extremities. Thrombo-angitis obliterans is easily excluded for there is often a history of intermittent claudication when the muscle circulation is involved or of migratory phlebitis.

It is almost always unilateral to begin with, becoming bilateral sooner or later. Almost all cases have a polycythaemia (Saint, personal communication). An anaemia was first seen in both my cases. The only two points which Buerger's disease has in common with these cases are that the patients were relatively young adults and were all males.

Ergot poisoning has to be considered. There is usually a history of the patient's having taken the drug, or of other cases occurring in the community. In the cases recorded, however, no other sufferers with gangrene were observed in the areas from which they came. In ergot poisoning, in addition to the gangrene, nervous symptoms may appear. In my cases, however, there were no neurological changes. In ergotism the gangrene may affect not only the toes but also the fingers, and is usually delayed for weeks. In my cases the onset was rapid and only the lower extremities were affected.

Exposure to excessive cold may result in gangrenous changes in the extremities. Abramson *et al* (1946) describe illustrative cases with symmetrical gangrene of the toes and feet bearing a close similarity to the cases described in this paper. Trench foot is usually seen in those compelled to remain in trenches for a prolonged period during which the extremities are exposed to a damp and very cold environment. There was nothing, however, in the history of the present cases to attribute the gangrene to such a cause.

Lewis (1936) describes two interesting forms of symmetrical or bilateral gangrene which bear a great similarity to my cases. The first form is referred to as "bilateral gangrene of the digits in the young," and the second as "bilateral gangrene in the digits occurring in the elderly."

In the former group children and young adults are affected, both sexes equally. The origin of the condition is obscure. It usually affects relatively young people with no previous history of vascular disease. At the time of onset, however, malnutrition or some other condition causing chronic ill-health is present. It may, on the other hand, develop during an acute infection such as pneumonia or typhoid fever. The onset is apparently sudden, without warning, and several fingers or toes are affected. These become discoloured within a few days. Tissue at the tips of the toes is lost, the gangrene usually being dry. Occasionally it may extend to the base of the distal or middle phalanx. The disease is bilateral and often strictly symmetrical. The main arteries are unobstructed. Lewis considers that the condition probably results from damage to the intimal coats of the digital arteries, with resultant thrombosis. My cases appear to differ from these in that they had a preceding history of pain and oedema in the affected areas, and that in two of them the gangrene extended well beyond the toes, thus being more extensive than in the disorder described by Lewis, also, the fingers were unaffected. The similarity between his cases and mine lies in the fact that a single attack with symmetrical distribution occurred in those generally poorly nourished or in a patient during the course of or following an acute condition.

In the second group described by Lewis—bilateral gangrene of the digits in the elderly—an associated disease, such as cancer, tuberculosis, high blood pressure, or diabetes was present with the gangrenous disorder. The fingers often become discoloured without warning and gangrene soon follows. The gangrene is often associated with much pain. Lewis supposes that the vessels show intimal thickening, due to nutritional changes. This leads to multiple arterial obstruction.

It is not possible to give a cause for the cases I saw over the past four years. The exact symmetry of the affection would suggest a toxic disturbance or some general disorder

such as a deficiency disorder. I doubt if ergot was the cause of the gangrene, since one of the cases was admitted with cerebral malaria, and developed the condition in hospital. Quinine, however, was administered to this patient and may have produced a spasm of the vessels.

Pellagra, ariboflavinosis, hypoproteinaemia, and other disorders of nutrition are common in the African. Case 1 showed signs of pellagra. It is possible that the gangrene may have resulted from vascular occlusion, a direct result of a nutritional disturbance in the vessel wall. This possibility is not altogether improbable in view of the reports on the development of gangrene in the extremities seen among prisoners of war in the Far East. Recently Page (1946) reported on the findings on 2,000 prisoners of war from Hong Kong. Among these a certain number with painful feet and signs of deficiency in the vitamin B complex developed gangrenous changes in the toes and feet. Page reports, too, that Prof. Kinoshita of Osaka University studied these vascular changes seen among Japanese soldiers returned from the South Pacific and found definite thickening of the vessel walls with narrowing or obliteration of the tissues of the small arteries of the feet and legs.

Summary

Six cases of gangrene of symmetrical distribution and extent occurring in the African are described. In four the gangrene was limited to the toes, but in two the gangrene was more extensive.

The condition sets in simultaneously on each side, first with oedema, followed by pain and finally gangrene.

My thanks are due to Prof. C. F. M. Saint for kindly examining the two cases described in detail and for his suggestions as to the differential diagnosis. I am grateful to Dr. R. M. Morris, Medical Director, Southern Rhodesia, for permission to publish this paper.

Medical Memoranda

Acute Infectious Lymphocytosis

Steigman's (1946) account of infectious lymphocytosis has drawn attention to the importance of this condition in children, especially in the differential diagnosis of infectious lymphocytosis and acute leukaemia, and prompts me to report a case of the acute form, as very few have so far been recorded in this country. From a perusal of the literature infectious lymphocytosis would appear to be a disease of recent origin though before Carl Smith recognized it as a separate disease entity in 1941 it was probably confused with infectious mononucleosis. No cases even suggestive of the condition seem to have been reported before 1939 and indeed, only a handful of cases were to be found in the American literature, and apparently very few elsewhere until Finucane and Philips (1944) described an epidemic of 21 cases in a children's sanatorium.

CASE REPORT

The patient, a boy aged 7, first attended the children's department of the London Hospital on Oct. 15, 1946, with a history of diarrhoea for five weeks. There was slight abdominal pain, he passed frequent motions containing a little mucus, and he complained of sweating at night. The only abnormality noted was moderate enlargement of the left cervical glands. Rectal swab and x-ray examination of the chest were negative. On Oct. 25 blood examination revealed a white cell count of 30,600 per c.mm. (75% normal small lymphocytes) and haemoglobin 85%. At the age of 4 he had had whooping cough and two years later he developed mumps. An uncle had died of pulmonary tuberculosis when the boy was 1 year old, but there was no history of contact.

On admission for further investigation the boy felt perfectly well, the diarrhoea having ceased. He was thin and rather pale, and was afebrile, pulse 90. The tonsils were slightly enlarged as were the glands of the left side of the neck, which were discrete and rubbery. The spleen and liver were not palpable. There were no symptoms or signs referable to the nervous system. No other abnormality was noted, except that on Nov 7 the white cell count was 52,300 (76.5% small lymphocytes). The Wassermann reaction, Minnioux test, and Paul-Bunnell reaction were all negative.

By Nov 20 the white cell count had dropped to 11,100 (51% small lymphocytes, 40% neutrophil polymorphs and 3% eosinophils). He was then discharged to the out-patient department, and on Nov 26 the white cells numbered 13,300 per cmm (lymphocytes 25%). He felt well and there were no abnormal signs.

COMMENT

This case is typical of infectious lymphocytosis, especially in the mild abdominal symptoms, the paucity of physical signs, the cervical adenitis, the leucocytosis with relative and absolute lymphocytosis due to increase in normal small lymphocytes, lasting three to five weeks, and the negative heterophile agglutination test. If the disease is due to a virus as is to be supposed in the absence of a demonstrable bacterial agent, the blood changes are very unusual, since viral infections are characterized by leucopenia, the apparent lymphocytosis being only relative. As in the cases reported by Finucane and Philips a mild eosinophilia appeared as the total count fell.

I should like to thank Dr Kenneth Tallerman for permission to report this case, which was under his care.

Pseudo-Hypertrophic Muscular Dystrophy

The commonest type of muscular dystrophy seen in clinical practice is pseudo hypertrophic muscular dystrophy, and its features are fairly constant. The following case is of interest because of the late onset of symptoms and the slow progress of the disease.

CASE REPORT

The patient, a man aged 68, was admitted to hospital complaining of difficulty in walking. At the time of admission he could walk only with the greatest difficulty and the slightest obstruction to his progress caused him to lose his balance. The first symptoms appeared at the age of 28 when he experienced difficulty in climbing stairs. He was then employed as a locomotive fitter, an occupation involving a considerable amount of climbing on and off engines. The progress of the disease was so slow that he was able to continue at his employment until he retired at the age of 64.

Since his retirement, however, a rapid deterioration in his condition has taken place, until now, at the age of 68 he is almost completely crippled. He is an only son but a maternal uncle had been similarly affected since childhood. The patient has two sons aged 28 and 30 who so far show no signs of the disease.

Examination revealed the characteristic combination of muscular hypertrophy and wasting found in this condition. Pseudo hypertrophy was present in the gastrocnemius, deltoid, and infra spinatus muscles. Wasting was evident in the supraspinatus, pectoralis major and biceps brachii, but there was no involvement of the masseter or of any of the other facial muscles. The pupils were central, circular, and equal, and reacted to light and accommodation. The cranial nerves were normal, the knee jerks could not be elicited, but the ankle reflexes were present, and the plantar responses were flexor. There were no signs of disease in the cardiovascular, respiratory or alimentary system. The Wassermann reaction was negative, and a glucose tolerance test normal. Section of the pectoralis major showed an almost complete absence of muscle fibres with replacement by fat. Section of the gastrocnemius revealed swelling of the muscle fibres with proliferation of the sarcolemmal nuclei.

COMMENT

Pseudo-hypertrophic muscular dystrophy is said to have the least benign course of all the dystrophies, and generally shows a progressive deterioration. Death usually ensues in 10 to 15 years from secondary pulmonary complications following paralysis of the respiratory muscles. Most cases of this type of dystrophy start about the middle of the first decade. A precocious onset of symptoms is said to forebode a bad prognosis

with a rapid deterioration and conversely, a late onset often indicates a more favourable course. In the present case the onset was delayed until the age of 28, and the course of the disease has so far extended over 40 years. Moreover there seems to have been an arrest of progress during 36 years.

It is likely that, had the patient been seen 10 years ago recovery might have been reported and this is a possible explanation of some of the cases of cure which have been recorded in the literature. The rapid progress of the disease at the end is also an interesting feature of the case.

Most of the cases in which arrest of the disease has taken place have been examples of the Landouzy-Déjerne type or of the Erb juvenile type. Since the essential pathology of the dystrophies is the same it is to be expected that a similar course would be followed by other types of dystrophy, and the case here described is a good example of the slow course and temporary arrest seen in the other types of muscular dystrophy.

I wish to thank Dr H H MacWilliam, medical superintendent of Walton Hospital for permission to publish this case.

V K SUMMERS M D, M R C P

Visiting Physician, Walton Hospital

Empyema of Frontal Sinus simulating Osteomyelitis

In the following case the history and clinical signs resembled osteomyelitis of the frontal bone, and for that reason I submit it for publication.

CASE REPORT

Madame A, aged 50, was admitted to hospital complaining of a discharging sinus above the right eyelid for five months. There was no pain and the discharge was preceded by a swelling of the right upper lid for two weeks. She had had headaches over the right side of the forehead for one year. Six years previously she had had similar headaches and swelling of the right upper lid, but no discharge.

On examination a narrow sinus discharging yellow pus was observed immediately beneath the centre of the right eyebrow. *Staphylococcus aureus* was found on direct examination and culture. A probe was passed easily through the sinus, which proceeded above the superior orbital rim in the direction of the posterior ethmoidal cells for a distance of 2 in (5 cm) over the right frontal surface of the frontal bone. There was slight depression, oedema, and tenderness on pressure. Skiagrams showed what appeared to be an abnormally large right frontal sinus, the left frontal sinus was apparently absent. The right superior orbital margin was depressed about one third of an inch (0.8 cm) and marked widening and shortening of the right superior orbital fissure were found. There appeared to be a doubtful sequestrum at the medial margin of the sinus. A lateral view showed an abnormal depth to the sinus.

The frontal bone was approached through a Howarth incision opening the discharging sinus. The orbital rim and floor of the frontal sinus were intact but very thin. The pus was evacuated through the discharging sinus, and an empyema of the right frontal sinus was found occupying an oval cavity about $3\frac{1}{2} \times 2 \times 2$ in ($8.75 \times 5 \times 5$ cm) which had completely eroded the roof of the orbit to the level of the superior orbital fissure. The pulsation of the frontal lobe of the brain and meninges was clearly palpable through the mucous lining of the empyema. There was an erosion of the anterior wall of the sinus, and through this the sinus discharged.

The fronto nasal duct was enlarged in routine Howarth fashion and the anterior ethmoidal cells were removed. A $1\frac{1}{2}$ in (1.25 cm) drainage tube was inserted into the wound through the enlarged fronto nasal duct to the nostril. A full course of sulphathiazole and 3 000 000 units of penicillin were given over a period of 4 weeks. Recovery was uneventful.

PATRICK J McNICHOLAS M Ch D O M S

Irish Red Cross Hospital
St L6 Francc

At the Eighth Congress of Scientific Films held in Paris in October, 1946 the Institut de Cinématographie Scientifique Paris and the Scientific Film Association, London, and observers from UNESCO, Czechoslovakia, Poland, Sweden, and the U.S.A., agreed that it was necessary to establish an international scientific film association. After preparing a draft constitution, the British and French organizations have been meeting in Paris to complete arrangements for an inaugural congress, to which all countries are being invited. This will be held in Paris at the beginning of October 1947. It is hoped that the proposed association will assist in the provision of a number of practical and urgently needed services.

Reviews

EDUCATION FOR MEDICINE

Medical Education and the Changing Order By Raymond B Allen, M.D., Ph.D. (Pp 142 8s 6d) New York The Commonwealth Fund London Geoffrey Cumberlege (Oxford University Press) 1946

The practice of medicine reflects the philosophy of its age. In this challenging monograph Dr Raymond B Allen, a medical educationalist of wide experience and now President of the University of Washington, surveys the problem of medical education in the post-war world. He necessarily poses more questions than he answers, for medical education is an experimental art. There is no science of medical pedagogy, curricula are never final. Only programmes of instruction based on the knowledge, experience, imagination, wisdom, and courage of individual teachers and taught in medical schools of high quality will achieve success. Since, as Santayana wrote, "Those who cannot remember the past are condemned to repeat it," Dr Allen sketches first the historical development of medical education. For him, as for others, medical education begins with the child and does not end until the physician has retired from active practice. The study of medicine, he believes, should include that of life in all its aspects—physical, psychological and social. The physician should be so trained that he is competent to apply new knowledge in any branch of human activity to healthy living and to the prevention and cure of disease, he should co-operate fully with all those agencies whose aim is the provision of adequate medical services for the people. Therefore the student, before entering a medical school, should be an informed and cultured person with a sound knowledge of men and the world. He should be well grounded in the natural and social sciences, the methods of science and the humanities, he should have formed habits of study, industry, honesty, dependability, friendliness, decency, and courage which should endure throughout his life. (It might in passing be noted that the medical student in the United States enters his medical school at the age of 21-2 years, after a three- to four year college course, in Britain the student usually begins his medical studies at the age of 18.)

Dr Allen makes a plea for emphasis, in the early undergraduate period, on broad principles and general ideas and concepts, but even here illustrations should be chosen which have application in the clinical field. Students should at this stage be taught where to find detailed information on any special topic and how to use a library. He pleads forcibly that the responsibility of the schools is to teach an *integrated medical science* and not the separate disciplines of anatomy, physiology, pathology, etc., as such. To achieve this unified course a new type of 'Faculty of Medicine' is envisaged in which should be vested the full and final responsibility for the undergraduate teaching programme. This faculty would specify what no committee has yet drafted in detail—namely, (1) the fields of knowledge to be covered (2) the special skills to be acquired and (3) the type of integration to be achieved. Heads of departments would ensure that their most gifted teachers were available to carry out the faculty's programme. Dr Allen emphasizes that the student in his clinical studies must have a sense of continuity in the medical care of a patient in order to acquire a lasting knowledge of the natural history of disease and experience in how patients, as well as doctors and nurses, strive with illness. He deprecates the "snapshot" impressions of large numbers of patients seen only occasionally which is encouraged by many methods of clinical instruction and he rightly condemns the increasing tendency of clinicians, and hence of their students to rely more and more in diagnosis on laboratory reports and less and less on clinical judgment based on the history, examination, behaviour, and social background of the patient. It takes a man, not a machine to understand a man. The physician must be a humanist if he is to fulfil his vocation.

The author commends the step towards independent responsibility for the welfare of patients which an internship affords and critically assesses its various types. He also makes

many wise observations on other topics—examinations, post-graduate education, and research. Throughout the book he stresses that medicine is a social science serving humanity. It is not enough that doctors should know about disease, they must, as Alan Gregg writes, care about it. This is the orientation in medical education which Dr Allen commends to his colleagues in American medical schools. It is one on which we in Britain would do well to ponder.

HENRY COHEN

DICHROMATIC VISION

Retinal Structure and Colour Vision. A Restatement and an Hypothesis By E. N. Willmer, Sc.D. (Pp 232, illustrated 21s) Cambridge The University Press 1946

After reading Mr Willmer's book we could not help reflecting on those happy bygone days before the last war when, turning aside from the commonplace three-dimensional world, men grappled with Einstein, relativity, and the fourth dimension. Suppose at that time some writer such as H. G. Wells had brought out a novel about a two-dimensional universe, it would have aroused great interest. He might have described how some scientists who had devised an atomic rocket of great power travelled in it to a distant planet. They landed safely, and discovered to their amazement towns consisting of flat houses with flat gardens. Flat boys and girls, with their flat parents, were all moving about rather like amoebae in the narrow space between two plane sheets of glass.

The analogy will be obvious to those familiar with current opinion on the physiology of vision, for losing confidence in the trichromatic theory of Thomas Young and following the lead of Prof Granit, of Sweden whose micro-electrode investigations on animals are well known, physiologists are examining tetrachromatic and even polychromatic theories for guidance. Now Mr E. N. Willmer presents us with all the pros, and many of the cons, of a dichromatic theory. His thesis is interesting and stimulating and a fitting record of his ingenuity and patience. The book is well written and attractively illustrated. The shades of colour in some of the plates are very pleasing.

H. HARTRIDGE

BEFORE AND AFTER OPERATION

Preoperative and Postoperative Treatment Edited by Lt-Col Robert L. Mason M.C., A.U.S., and Harold A. Zintel M.D. Second edition (Pp 584, illustrated 35s) Philadelphia and London W. B. Saunders Company 1946

A post-war edition of this excellent vade mecum for ward work is welcome. Considerably revised by Colonel Mason the co-author, and his New England collaborators, the work reflects the best in American pre-operative and post-operative management. Much of the detail is beautiful in its precision—the directions for shaving the wound area, for example, could not be more meticulous—and no practising surgeon could read the book without profit and enjoyment.

The viewpoint is essentially American, while this adds value to such sections as those on water and salt loss, on alkalaemia and on amino-acid feeding, some other sections suffer from their authors' inattention to foreign surgery. No Scandinavian work is considered and only one Canadian paper is quoted in connexion with heparin, and the chapter on post-operative pulmonary complications is similarly limited. The Australian methods of preparing the colon for excision are not mentioned and of forty one references in the section on blood transfusion only twelve, all American, are dated later than the beginning of the war. Indeed the whole subject of shock has been less diligently re-edited than other chapters. All the references in it are to pre-war work, and British contributions to the understanding of types of shock, irreversible shock, and the dangers of excessive transfusion have not yet displaced the older opinions about toxins and nervous mechanisms. Some of the authors trust too confidently in the work of the chemical laboratory—Maddock's formula for calculating the salt needs of a hypochlorhaemic patient from the plasma chloride, for example may cause grave error, and the hematocrit determination, blood specific gravity, and plasma protein as criteria of

dehydration are notoriously liable to mislead unless their fallibility is recognized.

However the defects of the book are inherent in its qualities. Not only is the biochemical basis of therapy and prophylaxis everywhere sound, but there is throughout a typically American insistence that no effort be spared to investigate the patient thoroughly to apply every pre-operative detail that will benefit the patient at operation and to be inspired with an unflinching care after operation for his comfort and safety.

IAN AIRD

PELLAGRA IN POWs

Pellagra in the Oto Neurology and Rhino Laryngology By Otto L. E. de Raadt M.D. (Pp 172 Fl 5.00 (Dutch currency)) Leiden University Press Leiden Available from N. V. Martinus Nijhoff, Lange Voorhout 9 The Hague

This is an English edition of a thesis presented at Leiden University, presumably written originally in Dutch. Dr de Raadt an ENT specialist was one of a group of Dutch medical men confined in POW camps in the Dutch East Indies and in this monograph he gives an interesting account of his findings based on the examination of 160 persons suffering from deficiency states in Bandoeng, Java.

Although the subjective complaints of vertigo, tinnitus and auditory impairment are among the commonest symptoms of pellagra and have been recognized from early times, we do not remember having seen before a detailed description of the objective findings in these cases when submitted to routine tests. As the author remarks, 'Strange is the absolute absence of any report of vertigo in pellagra in the oto rhino laryngological bibliography at the end of the thesis'. He also discusses the ocular manifestations and other coincident symptoms, particularly those generally considered to be caused by hyporiboflavinosis.

The following are some of the conditions that the author surveys: vestibular hyperexcitability for cold water nystagmus, hearing loss of perceptive type, Eagleton's symptom, Bing's ocular cogwheel sign, tinnitus due to deficiency, abnormality in the form of the pupils, hypo or achlorhydria, burning and pruritus in hands and feet, stomatitis, glossitis and pharyngitis. Unfortunately in Java, as elsewhere in Japanese POW camps satisfactory therapeutic tests could not be used, but it would appear likely that the deficiency responsible for the cases described by Dr de Raadt was of riboflavin and other closely associated vitamins of the B complex.

H. S. STANNUS

Those who knew Sir GEORGE NEWMAN debonair and versatile Chief Medical Officer of the Ministry of Health, only in that capacity will be surprised to find from *Quaker Profiles* that he has been a life long devotee of the Quaker way of life. His beliefs are set out in a series of descriptions of eminent members of the Society of Friends such as Fox the founder, Pennycuik the historian, and the Rowntree family. There are incidental references to eminent Quaker doctors such as Lister and Jonathan Hutchinson. These practical mystics showed by their lives that that kind of mysticism is not incompatible with eminence in business, literature, and science. The chapter devoted to Joseph Rowntree shows him as a pioneer in the scientific treatment of social problems. The Cardinal Tenets of Quakerism are discussed at some length, and among these the 'inner light' plays a prominent part. This mystical revelation it seems to the reviewer is really indescribable, though its reality to those who have experienced it cannot be doubted. The papers contained in the book (Bannisdale Press, 7s. 6d.) come mainly from *The Friends Quarterly Examiner* of which Sir George Newman has been the honorary editor for over forty years. They are characterized by the clarity and grace which we have long been accustomed to associate with the author's work.

Prof. Abderhalden wrote a book about the general principles of nutrition during the first world war *Die Grundlagen Unserer Ernährung und Unseres Stoffwechsels* (H. Huber Bern Swiss francs 8.50) which has passed through many editions has been brought up to date. It has the merit that the importance of energy is not obscured in descriptions of new discoveries and the author lays stress on the many stages through which food passes before it is actually used in the body. The account of the effects of deficiency of calories is scanty. He gives details of the technique of metabolism experiments.

BOOKS RECEIVED

This is not precluded by notice here of books recently received.

The 1946 Year Book of Obstetrics and Gynaecology Edited by J. P. Greenhill M.D., F.A.C.S. (Pp 655 21s) London H. K. Lewis 1947

Summarizes recent advances in obstetrics and gynaecology.

The Design of Experiments By R. A. Fisher, Sc.D., F.R.S. 4th ed. (Pp 237 12s 6d) London Oliver and Boyd 1947

This edition includes new material on orthogonal squares, on confounding with many factors, and on the fiducial limits of a ratio.

Genetics By E. Altenburg (Pp 452 16s) London Constable and Co 1947

An account of modern genetics for the student.

Penicillin Therapy By John A. Kolmer, M.S., M.D., F.A.C.P. 2nd ed. (Pp 339 \$6.00) New York and London D. Appleton Century Company 1947

This edition contains new chapters on streptomycin, tyrothricin, streptothricin and other antibiotics.

Handbook of Neurological Examination and Case Recording By D. Denny Brown M.D. (Pp 107 10s 6d) London Geoffrey Cumberlege 1946

An introduction to neurological methods for students and housemen.

Textbook of Obstetrics By Gilbert I. Strachan M.D., F.R.C.P., F.R.C.S., F.R.C.O.G. (Pp 771 45s) London H. K. Lewis 1947

A textbook for students and practitioners.

The Chemical Constitution of Natural Fats By T. P. Hilditch D.Sc., F.R.S., F.R.I.C. 2nd ed. revised (Pp 554 45s) London Chapman and Hall 1947

This edition includes new material on component acid data in lipid animal and vegetable fats, on component glycerides and on individual fatty acids.

Der Blutspender By Dr H. Willenegger and Dr R. Bittel (Pp 197 10 Swiss francs) Basle Benno Schwabe 1947

The technique of blood transfusion, with reference to its use in the recent war.

Harvey Cushing: A Biography By John F. Fulton (Pp 75 30s) Oxford Blackwell Scientific Publications 1946

A biography for the student and general reader with many photographs.

British Standards Institution Yearbook 1946 (Pp 296 2s. post free) London British Standards Institution 1946

Lists British Standards in numerical order, with a subject index.

Surgical Treatment of the Nervous System Edited by F. W. Bancroft, A.B., M.D., F.A.C.S., and Cobb Pilecher, M.D., F.A.C.S. (Pp 534 £5 10s) London J. B. Lippincott 1946

An illustrated textbook of neurosurgery for the neuro and general surgeon.

A Laboratory Manual of Vertebrate Embryology By F. B. Adams Stone Ph.D., and Waldo Shumway, Ph.D. 2nd ed. (Pp 90 12s) London Chapman and Hall 1947

Summarized information on the embryology of the frog, chick, and pig.

The Diagnosis of the Acute Abdomen in Rhyme By Zeta (Pp 88 5s 6d) London H. K. Lewis 1947

Abdominal catastrophes recounted in verse.

Nutritional and Vitamin Therapy in General Practice By Edgar S. Gordon M.D., Ph.D., 3rd ed. (Pp 410 27s 6d) London H. K. Lewis 1947

An account of vitamins and nutrients for the general practitioner.

Henry Sewall: Physiologist and Physician By Gerald B. Webb and Desmond Powell (Pp 190 16s) London Geoffrey Cumberlege Oxford University Press 1946

A biography, with photographs of the American physician.

LONDON

SATURDAY JUNE 14 1947

DISCUSSIONS WITH THE MINISTER

The Prime Minister announced in the House of Commons on June 9 that the Appointed Day under the National Health Service Act would be July 5 and not April 1, 1948. This will allow another three months for the setting up of the central, regional, and local machinery necessary for the operation of the new Health Service. It will also allow more time for the important discussions which are taking place between the Ministry of Health and the Negotiating Committee. This Committee, which could not be more widely representative, has undertaken a responsible task. Soon it will be in a position to put before the profession a statement of the way in which that task has been discharged. No news is not always good news, and in recent weeks some of our correspondents have taken as bad news the lack of any detailed statement about the progress of these discussions. Many doctors are worried about practices they have bought recently or practices they propose to buy. Assistants are not clear about their future prospects, and some of the recently demobilized medical men are at a loss as to their next step. An interim report in general terms may perhaps allay some of the anxiety felt by those readers whose letters we have published, and by many others whose inquiries and communications have not been attended for publication.

The National Health Service Bill, which first saw the light of day on March 19, received the Royal Assent¹ on Nov 6, 1946. There followed a great deal of vigorous controversy which culminated in a meeting of the Negotiating Committee on Feb 7. The Committee was then informed that the Minister of Health would like to enter into discussions and that he had accepted the conditions of the Negotiating Committee—namely, that such discussions should be comprehensive in their scope and should not exclude the possibility of further legislation². Discussions began almost immediately and have proceeded throughout on this comprehensive basis. The same conditions have been accepted so far as Scotland is concerned by the Secretary of State and discussions on the National Health Service (Scotland) Act, which received the Royal Assent barely a month ago³ have now begun.

Details were published in the *Supplement* (March 15, 1947) of six subcommittees set up by the Negotiating Committee. These subcommittees are concerned with general practice hospital and specialist services, public health, dental health, ophthalmic services, and superannuation. Each subcommittee has been actively engaged in parallel discussions with the Ministry. Each has impressed upon its officers of the Ministry, by explanation and argument,

the points of policy laid down by the Negotiating Committee. In some cases discussions have been completed, but other subcommittees, and notably the General Practice Subcommittee, are still hard at work. No precise details can be given, for obvious reasons. It is anticipated, however, that sufficient progress will have been made for each subcommittee to report back to the Negotiating Committee at a meeting to be held before the autumn. These reports will have to be considered carefully and as interlocking parts of a full and comprehensive scheme. It is probable that the Negotiating Committee will then seek a meeting or meetings with the Minister in order to press upon him all aspects of the considered views of the Committee, advised and instructed as it has been by all its constituent bodies. The next step will then be for the Minister to reply to these representations.

So far the details of the exchanges will have been confidential. It is inevitable that this should be so. At this point, however, discussions should have reached the stage at which the full story can be told to the whole profession. A summary of the representations made by the Negotiating Committee, together with the Minister's reply, will then be published. It will then fall to each individual member of the profession to exercise that judgment which must precede action. Local and central discussions and meetings and a plebiscite will provide the familiar democratic machinery for decision. The whole profession will decide by these means its future course of action. It is still not possible to lay down a time-table for these events. Two assurances can be given, however. Discussions have been completely comprehensive, and all along representations have been made with vigour, clarity, and determination. Discussions will soon be completed, and when they are the report made by the Negotiating Committee to the profession will be full and explicit.

WHITHER INDUSTRIAL MEDICINE?

After 1918 industry discarded its medical services. These were mainly in Government ordnance and filling factories which eventually closed as the need for munitions diminished. Industrial medicine was then limited to a study of occupational disease and first-aid requirements in factories¹. The amount of money spent on industrial health research was negligible, and no university provided teaching or any other facilities in the subject. Between the wars the number of factories with a medical service slowly increased, standards were set, and interest was stimulated. But not until 1940 had medicine in industry a real opportunity to develop, an opportunity which arose as a direct result of legislation introduced by Mr Ernest Bevin, then Minister of Labour.

It is now nearly two years since the second world war ended, but so far there is no sign of any appreciable decline in industrial health services. Everything points, indeed, to a further extension. Large firms are retaining their doctors, nurses, and dentists, and some of them are expanding their services. Certain new post-war organizations, such as B O A C and the Coal Board, have included

⁴ *Annual Reports of the Chief Inspector of Factories* 1919 and 1920

ical services in their planning from the beginning. Group experiments such as that sponsored by the Nuffield Foundation on the Slough Trading Estate are arousing widespread interest. The Ministry of Supply has formed a permanent medical service. Some universities have set up departments of occupational health and have appointed professors and lecturers. The amount of money spent on industrial health research by the Medical Research Council increases each year, no fewer than eight separate units now work mainly in this field, and new committees dealing with the subject have been created.² Recent legislation, notably the Disabled Persons (Employment) Act, 1944 and the National Insurance (Industrial Injuries) Act of 1946, will ensure for industrial medicine a permanent place in the health services of the country. The effect of the Industrial Injuries Act was discussed in these columns a few weeks ago.³ In addition the importance of industrial health services is now more widely recognized by the layman. A useful report from the jute industry⁴ was compiled by employers and employees in conference with Government officials. This committee's recommendations range over a wide variety of subjects but include the firm view that "every jute factory should be under the supervision of a medical officer" and that "a comprehensive scheme of medical supervision covering the whole industry should be developed." Working parties in other industries might profitably devote attention to similar points.

We publish in this issue at page 838 the inaugural address by R. C. Browne, who was recently appointed to the chair of industrial health at Durham University. He emphasizes that until recently "industrial health" meant merely "industrial toxicology." Now a broader view is being taken. Over the past thirty years there has been a great increase in research by committees, sometimes sitting at a distance from the problem under review. Industrial health research at the start of the recent war was largely a repetition of former work or was designed to re-emphasize principles already known. As Browne says, "We observed the melancholy but understandable spectacle in 1940 and 1941 of industry attempting to run in almost complete ignorance of what had already been discovered in the previous war." However, the needs of the armed Forces for up to date knowledge of the effects of modern mechanization on the individual fighting man had an important influence. These needs were well satisfied by groups of workers, and Service experience during the war was in many ways in advance of present civilian practice.

There are three main ways in which industrial medicine could expand—by extension of the present system, by the creation of a whole-time national industrial health service, and by a compromise between these two methods. Extension of the present arrangements, even aided by legislation, is open to criticism. The system is inadequate, because it is limited to the larger and more enlightened industrial concerns, most of them factories, and little concerned with other occupational groups. It is haphazard, because of widely differing standards of service, both administrative and technical. The methods of appointing industrial

medical officers—particularly those in a part time capacity, are open to abuse. It is also true to say that a number of employers still tend to give the minimum of co-operation. The costs of the service are met entirely by the employer at present, and it has been said, mainly by those with little day-to-day contact with men at work, that the industrial medical officer is therefore biased in his decisions. Evidence of this is hard to find.

The creation of a whole-time State industrial health service, perhaps good in theory, might provide an apparently easy answer. Difficult problems to decide—problems differing widely from those now arising in connexion with the new National Health Service—would be the method of finance, methods of control and by which Ministry, sources and recruitment of medical man-power, and, particularly, the place of the general practitioner in the service, the extent to which there should be technical direction and supervision of the doctor, conditions of entry into the service, educational facilities generally, and the more abstract but nevertheless fundamental problem of loyalty. How effective can a doctor be, as an instrument for promoting good relationships in a given group, if he has a major loyalty to Whitehall or to a regional committee? Other criticisms of a State service, already well aired in our columns, would no doubt also apply, of these the fear of red tape and of bureaucratic remote control would be outstanding. A recent report by the Royal College of Physicians of London⁵ advocates a national health service for industry, but only broad principles are stated.

"An Industrial Health Service should be planned in a bold manner without much regard for traditional arrangements. Legislation should provide for the needs of smaller industries and non industrial undertakings. The service should be an essential part of the National Health Service. The Chief Medical Officer of the Ministry of Health should be the Chief Medical Officer of the Industrial Health Service. There should be uniform conditions of service rates of remuneration, and pensions. The service should be organized on a regional basis. Whole time industrial health officers should be appointed for the larger industries, and in suitable cases there should be a combination of full time and part time service. But general practitioners will be the main body of the industrial health service. There would be obvious difficulties if they were employed by two separate Government Departments."

The third way in which progress can be made is by a compromise between the two schemes, so that the best features of each could be retained. By common consent the present standards of industrial health practice should be improved and extended. It is doubtful whether industry as at present constituted, would care to be saddled with yet another control—possibly of an inspectorate within its own gates. But it is ready to accept the principles of health supervision at work, and the workers themselves on many occasions have insisted on this, as recent pronouncements by miners and dockers show. The scheme should be comprehensive in that the needs of 18,000,000 employed people should, after study, be catered for. The need for careful planning is no less important than with a State service. One overall directorate might not be an advantage at this stage, but co-ordination is necessary. The whole-time industrial medical officer should conform to high

professional and technical standards and be acknowledged as a specialist. A small number of consultants should be available in the regions with both high medical qualifications and long experience. Whole-time specialists in industrial medicine might be encouraged to develop group practice. The part time medical officer, who will usually be a general practitioner, should satisfy certain basic standards before entry into the service, educational facilities should be provided by the universities to this end. The need for further professional links with regional committees should be explored. Any success that the industrial doctor may have had is largely because he has been accepted as part of the management. Both employer and employee then agree that his service is an integral part of the industrial system. The doctor obtains the confidence of all parties, he acts largely, and wisely so, in an advisory capacity, and his freedoms become those of any other independent medical man. It has been stated⁶ that whether industry is publicly or privately owned its directors must be appointed by and answerable to the owners and not to the workers. This same principle should also apply to the medical advisers to industry.

The future development of industrial medicine depends for success on the technical skill of its practitioners. The saving of working time by competent nursing and casualty services is one obvious contribution, as is straightforward advice on health matters in collaboration with general practitioners and hospitals. The ancillary services, providing advice and treatment on dental, ophthalmic, and more recently ear and throat conditions, have also proved their worth, their expansion to cover the smaller working units and groups might be developed in collaboration with the new regional hospital boards. But these matters are largely concerned with curative medicine. The industrial health officer must go further into the fields of prevention, medical sociology, and the promotion of health. He must forge close links with personnel officers, industrial psychologists, and others. In this way he can make a positive contribution to the economic well-being of the group. Questions associated with toxicology and hazard control—for example, the health problems arising out of atomic and supersonic developments—require the close co-operation of the engineer and the physicist, and will always arise with new advances in science. The study of the incidence of injury in different occupational groups and in varying accident situations requires help from statisticians, if the information thus obtained is to be exploited fully in the wide field of accident prevention. Industrial contributions to rehabilitation, including the placement of handicapped persons and methods of linking hospitals more closely with industry on lines similar to those suggested by R. C. Browne, require close attention. Methods of matching the man to the job and so placing individuals in occupations for which they are physically and mentally suited involves co-operation with personnel officers, works managers, and engineers, as well as with medical practitioners and hospitals, techniques of job description and job analysis have still to be developed and may well provide another valuable tool for the industrial physician.

Finally, there is the continuing health supervision of juveniles entering employment. Apprenticeship schemes have done much to provide vocational supervision. There is an equal need for the health supervision of the school to be continued into employment. To be successful this supervision must define health in its widest sense and include a close study of the social, economic, and even moral issues that so frequently arise. In this field alone industrial medicine could make a significant contribution to positive health.

SPRAY-DRIED EGG AND FOOD-POISONING

The relationship between eggs and salmonella food-poisoning has been discussed before in these columns,^{1,2} but it was not possible to give the full story because the facts from the English side were not available. Only a few experts dealing with the problem were aware that the extensive introduction of dried egg powder was followed by a great increase in outbreaks of salmonella food-poisoning, no information was given to the general public or indeed to the medical profession. Now the Medical Research Council has issued a special report on the subject,³ which includes details of a number of investigations by various bacteriologists. Two of the four reports are concerned with the bacteriology of dried egg and salmonella infections in man associated with the consumption of dried egg. The predominant bacteria in dried egg are enterococci and aerobic-sporing anaerobes, coliform organisms are present in every sample but only in small numbers. The significant finding is that in 754 or 9.9% of 7,584 samples examined, organisms of the *Salmonella* group were isolated. Since the media used were not suitable for their growth this excludes the comparatively harmless *Salm pullorum* and *gallinarum* types, which one would expect to find as their relationship to fowl diseases is well known. This high proportion of positive findings varied with the country of origin, being in dried egg from USA 11.1%, from Canada 4.1%, and from the Argentine 10.5%. While 33 different *Salmonella* types were isolated, 6 types were most frequently seen, all of them new strains not previously found in this country or associated with salmonella disease. These new strains are *Salm oranienburg* isolated 245 times, *Salm montevideo*, 139, *Salm meleagridis*, 117, *Salm tennessee*, 90, *Salm bareilly*, 82, and *Salm anatum*, 30 times. The most common food-poisoning strain, *Salm typhi-murium* was also isolated from 30 samples.

The report on salmonella outbreaks in man shows clearly that the extensive retail distribution of dried egg coincided with a marked rise in outbreaks of salmonella food-poisoning. In 1944, for example, there were 454 such outbreaks reported, a figure higher than the total for the whole of the seventeen previous years. As the authors of the report point out, this indicates some new source of infection, and the facts suggest that dried egg powder is this new source. This suggestion probably received the strongest confirmation when the *Salmonella* strains from these outbreaks were typed. There were 10 new types in

¹ *British Medical Journal* 1946 2 583

² *Ibid* 1947 1 456

³ *The Bacteriology of Spray-dried Egg with particular reference to Food poisoning*. By various authors. M.R.C. Special Report Series No. 260 1947 London, H.M.S.O. 15

1942 8 more in 1943, and another 6 in 1944. Of these new types the six commonest in order of frequency were precisely the six already mentioned as those most often isolated from dried egg. Complete proof that dried egg is the vehicle would require demonstration of its connexion with each outbreak notified. Owing to war conditions and other influences this was possible only in a few outbreaks, but in a number the connexion was established, and in the present report four such outbreaks are detailed. These new strains gave rise to much the same clinical features as the older long-recognized types.

The general public is mainly concerned with the vexations of rationing. The medical profession has to consider the possible effects of new foods and new food habits in relation to illness. Dried egg is a comparatively new food, and communal feeding is a comparatively new habit. The increasing use of British restaurants, school and factory canteens, and the like carries with it greater risks than previously of a considerable spread of infection from contaminated food. Much more attention has been paid to this problem in America, and investigators there have standardized bacteriological methods of assessing the efficiency of utensil-cleansing, have laid down the factors essential to an acceptable standard of sterilization, and have prescribed sound methods for the elimination of infected food-handlers. In this country we lag far behind. Little work has been done on this subject, and the illuminating paper by Hutchinson⁴ described one of the very few investigations made in Great Britain. It disclosed many unsatisfactory features which would not be tolerated in the U.S.A. and it emphasizes the need for further investigation and for the setting up, for general guidance, of standards of cleanliness and sterilization. Communal feeding has probably come to stay, and an authoritative committee to advise as to standards, technique, and other matters is an urgent need.

The introduction of foods such as dried egg and dehydrated vegetables should also be studied in relation to the spread of pathogenic organisms. Clearly the risk of food-poisoning from dried egg is a real one. An important part of efficient public health administration is to weigh up potential risks against known advantages, and it is not sound administration to reject a method merely because it involves a small risk. This administrative problem is faced fairly in a short appendix to the recent report contributed by the Ministry of Food. The Ministry makes out a strong case on the nutritive and economic sides for the importation of dried egg. It admits the infective risk but claims that it is a small one. Between 1942 and 1945 the Ministry imported 244,000 tons of dried egg and argues that against this quantity the ascertained cases of food-poisoning do not loom large. It goes further and discusses what can be done to reduce the risk. A specification that *Salmonella* group organisms must not be present was found impracticable. Experiments were then made on the effect of cooking, and the results are set out in the body of the report. "Numerous experiments showed that scrambled egg and omelette prepared from freshly reconstituted dried egg were free from demonstrable living

salmonellae, but that if the reconstituted egg was incubated for some hours so as to allow bacterial multiplication cooking could not be relied upon to kill all salmonellae present." Advice on the need to cook as soon after reconstitution as possible is set out on, for example, all leaflets to caterers. However, the statement quoted on the effects of heat treatment hardly justifies the light-hearted pronouncement "It may be concluded that if dried egg is effectively cooked immediately after reconstitution the risk of salmonella infection therefore does not arise." The risk exists and the Ministry of Food is probably right to take it, but it would be better to recognize its existence and point out that it can be minimized by suitable methods of cooking. The short introduction by the late Dr R. B. Haines and Prof. G. S. Wilson gives clearly the scientific basis on which the use of dried egg was continued after the risk was known, but it does not seek to imply that all risk can be removed. One method of prevention which does not appear to be mentioned in the report is by improvement designed to exclude *Salmonella* organisms at the places of production and drying. No doubt this was considered outside the scope of the report, but it is a promising line and already a good deal is being done, for example, by the exclusion of dirty eggs.

MEDICAL SERVICES IN DENMARK

We begin this week the publication of a short series of articles on the medical services of Denmark. Dr Gerald Evans (*Supplement*, p. 119) records an Englishman's impressions gained during a recent visit to Copenhagen. He will be followed in later issues by Danish physicians describing the conditions of general practice, the hospital system, the public health service, educational facilities, and the State Serum Institute—this last an organization whose fame as a scientific institution, a central epidemiological research laboratory, a diagnostic service, and a factory for the production of sera and vaccines has gone far beyond the confines of Denmark.

The Scandinavian countries have much to teach the rest of the world in the various fields of social welfare. They are in advance of most other European countries in education, sex equality, co-operative enterprise, infant and maternal welfare, public health, and social progress generally. They are of course small countries in which social experiment is easier than among vast populations with a varied industrial pattern. The population of Denmark is less than that of the county of London, and, apart from Copenhagen, only one town has many more than 50,000 inhabitants. Among a well-organized people, roughly half-rural and half-urban, the conditions seem to be almost ideal for social advance. Moreover it is important to remember that the Danes are a well-educated people. The fact that education is a necessary basis for national health measures is not always appreciated. Denmark, which had compulsory education, at least on paper, two hundred years ago, is in the vanguard of Scandinavian countries in the development of adult education. Its residential high schools for people up to 25 receive State subsidies but have perfect freedom and an undictated curriculum, and they are not predominantly vocational. By these and other means, including progressive and co-operative movements, the Danes have acquired a strong community sense, have learned the advantage of working together, and have come to understand what co-operation requires of the individual.

of our own National Health Service is to be a success the people must understand it, its need and value, its means and aims. Without such an understanding regulations and disciplines will count for little—something to be evaded rather than the leading strings to a healthier society. It is no less true for its patients than for its doctors that a National Health Service must be accepted rather than imposed, and we may regret that our Government, so energetic in legislation, while it has prepared a Service for the people, has devoted little attention to preparing the people for the Service. Many still believe that the service is a system of "free doctoring" and free everything else to do with health. They should be told that its success will depend largely on their own understanding and proper use of it, and also that it is not "free" but that the whole community is footing the bill.

The National Health Service in Denmark is a very different organization from the new British scheme. It was founded in 1909 and reorganized and adapted to the latest public health developments in 1932. Its functions are advisory, supervisory, and administrative. In one respect it resembles the General Medical Council, for it authorizes both general practitioners and specialists to practise their profession, but it also advises local public health authorities and the public generally in all medical matters, and supervises public health, nursing, and hospitals. The provision of hospitals for the people as a social task was laid down by ordinance as long ago as 1806. The onus of providing such hospitals was laid not on the State but on local authorities. The result is that Denmark now has a uniform and efficient hospital system, with hospital treatment available to any person who needs it, irrespective of means or social position. Nine out of ten hospitals belong to the bounty or city communes, and these municipal or county hospitals, as we should call them, have gained the regard of the people in the same way as the voluntary hospitals of this country. Perhaps it is because the municipal hospital is a recent growth in Great Britain, and some recollection of the old Poor Law Infirmary still remains, that these hospitals in spite of the excellence of many of them, have not yet evoked the same pride and affection, for the feeling of a community towards its hospital may not depend on the mode of financial provision for its maintenance. It is, or it should be, the people's own hospital, whether it is supported by the rates or by their voluntary contributions.

The medical profession of Denmark remains a free profession. The doctors have not been turned into Civil Servants, they have not even adopted a system of group practices or health centres, though Dr Evans describes the arrangement whereby people unfortunate enough to be taken ill after 8 p.m. may have a strange doctor to attend them. The only respect in which the Health Service seems to act compulsively towards doctors is in requiring them to send any notifications or reports which it considers necessary. The Danes have endeavoured to maintain the family doctor principle—that is each family has its regular doctor, one who knows not only the constitution and history of each individual in the family but his domestic and economic background. That principle is imperilled not so much by legislation as by the increasing specialization of medicine. In Denmark the sickness benefit club service which for over half a century has been providing free medical care for practitioners was planned from the start as a family doctor service including children under 15, and was not restricted to wage-earners. It is to the general practitioner that the application for medical attendance is made and through him the specialist is consulted and admission to hospital arranged. There is organized collaboration between general practitioners and hospitals, specialists, and

laboratories. It is said that the system is working well and there is no disposition to change it. In the hospitals—more so outside Copenhagen than within it—discussions and conferences take place between the hospital staff and local practitioners, and the latter receive reports on their discharged cases.

The Danes have succeeded in maintaining a system of individual medical practice, free from political pressure and interference by lay authority. The family doctor system is being carried out more consistently in Denmark than in any other country, although specialist medicine is of a high order. The family doctor system may not satisfy the departmental mind, may not be liked by those who tend to think of human beings in terms of statistics or of mere numbers, but it does represent the most human approach and the most effective approach in medical practice.

SCANDINAVIAN POLYCLINICS

In June, 1946, Danish, Norwegian, and Swedish representatives met in Copenhagen. A long report on this meeting¹ devotes much space to a discussion on the evolution of medical practice in health centres run as polyclinics.

Polyclinics are operated in the larger towns in Sweden and at the Universities of Uppsala and Lund. The largest polyclinics are directly linked with the hospitals whereas some of the smaller polyclinics are in this respect independent units. The former are usually staffed by the junior members of the hospital service, whereas the latter are in most cases in the charge of a specialist who gives part-time service. Originally intended only for the poor, Swedish polyclinics have come to be patronized more and more by the well-to-do who, in return for an increasingly elaborate service, pay fees for each attendance and a supplementary fee for radiological examinations and the like. A report from the surgical side of the Sahlgrenska Hospital shows that the average daily attendance at its polyclinic, staffed by two doctors, was 216 the record being 325 attendances in one day. In the course of four hours a day, these two doctors attended patients at the rate of 2.2 minutes per patient. The work included suture of recent wounds, dental extractions, applications of plaster-of-Paris, removal of small tumours, injections, aspirations, scrutiny of skiagrams, writing prescriptions and directions for special examinations, and communicating by letter or by telephone with other doctors with patients, and with their relatives. Though the rhythm of this particular polyclinic may have been exceptionally hectic, it is illustrative of a very definite trend.

It was hoped that polyclinics would ease the pressure on hospital beds but experience has shown that the hard-worked polyclinic doctor when confronted by an obscure case or one requiring much examination, is apt to send many of his patients to hospital, whereas a general practitioner has more time in which to keep his patients under observation at home. One of the Swedish delegates deplored the tendency on the part of the public at the present time to undervalue the human element provided by the individual doctor practising medicine as an art and to overvalue the technical side of medicine. Formerly the patient with a cold in his head went to bed with a bottle of brandy beside him. Now he lies himself to a crowded waiting-room at the polyclinic where he broadcasts his infection. On the other hand, a recent statistical analysis in Stockholm has shown that attendances on individual doctors including private practitioners, greatly outnumber attendances at polyclinics.

A PATIENT'S EXPERIENCE OF ECT

[From a Correspondent]

In view of Dr D W Winnicott's emphasis on the need for further study of patients' own reactions to physical therapy of mental disorder (*Journal* May 17, p 688) some account of the experience of a patient may be of interest. I am a writer by trade. My symptoms were I understand those of a mild depressive illness. I felt frustrated in the extreme brooded over past events was at times deeply depressed for periods of as long as two days at a time, and was liable to great irritability which I kept under control except in so far as it sometimes broke out in speech, accompanied by aggressive and exaggerated negativism in argument. That this condition had developed from a deep seated origin was indicated by the fact that I had stammered rather badly from infancy—i.e., over 45 years. In general, I found great difficulty in thinking and working on the ordinary superficial level usual in most occupations while lacking the specialized training which might have enabled me to direct my tendency to deeper thinking into some canalized and thus fruitful employment. This must be a common difficulty of the type of mind so well described by C E Montague—a mind which has 'a proneness to revel and bask in its own sense of fact'. The mildest depression greatly accentuates the disability of this type of person, I imagine.

I was sent by an ex-Servicemen's society for treatment, and up to the time I attended the clinic I had no knowledge of the physical methods in use. I had, however always taken a great deal of interest in psychology since making acquaintance with the subject at university 25 years ago. I knew enough of the general principles to publish an article on 'The Psychology of Road Accidents' in a leading review over ten years ago.

Experience of Treatment

I received two ECT treatments at a large clinic under the assistant director (whom I will call Dr X), and at the present date, after about 14 months, I still retain the following benefits: considerable but not complete relief from the stammer, complete relief from excessive irritability, somewhat improved capacity for work, a change from what seemed to me moods of the deepest depression to a less frequent and much shallower depressed mood, complete relief (to my great surprise) from a minor skin affection of some ten years' standing which had resisted other treatment.

My experience of treatment was as follows. At a preliminary interview Dr X asked me to send him written accounts of my history, family background and circumstances. He gave me a physical examination of the usual kind. I sent him a frank account of myself, and he then gave me a lengthy interview which included questioning under a drug injected into each arm. These injections temporarily eliminated the stammer.

He then, somewhat to my surprise, sent me home with two technical volumes—one a standard manual on depression, the other the bound papers of the Society of Psychological Medicine containing several papers on the various physical treatments. I, like Dr Winnicott, was deeply shocked at the idea of leucotomy and disliked what I read of cardiazol more than I disliked the idea of ECT. Perhaps a layman or a psychiatrist with a special interest in perfection of mind may instinctively object to these treatments just as a dancer or athlete, with a special interest in perfection of body, might instinctively object to quite ordinary surgery. I was thus enabled to form my own opinion of the treatment and whether I wished to undergo it. Admittedly the evidence was empirical, as it must be for the layman—and often for the ordinary practitioner—even in the case of a common aperient.

Dr X then interviewed me again in company with another patient who had developed a stammer after prisoner-of-war experiences. He explained the mechanism of aggressiveness and how in man it was expressed in speech. Later seeing me alone he prescribed six ECT treatments. I asked if there were any risk of change of personality character, or temperament. He assured me that the only effect was to restore the distorted personality to normal. I mention all this to show that in my experience at any rate the psychiatrist administering physical treatments is not necessarily the dangerous type rightly feared by Dr Winnicott who may press buttons or give injections without careful regard to the psychical factors.

I approached the treatments with much the same attitude as I take towards a dentist's chair. I knew as much as a layman could learn of what to expect, I thought I had satisfying evidence that consciousness was instantly obliterated, that risk of injury was negligible and that there was a high probability of benefit. In the event this evidence was confirmed by experience.

I disliked the form of restraint used but accepted it as one does a dentist's gag. My last sight of anything was Dr X, a tall upright and commanding figure standing just within my line of vision (I shall refer to this later). I then knew nothing whatsoever until I awoke some hours later from what seemed to have been a natural and refreshing sleep. I soon discovered some stiffness of the back and some pain near the temples on moving the jaw. However, I immediately knew that something important and good had occurred. A nurse was at the bedside, and I said to her: 'That was very clever of you.'

I felt light and easy in mind—nearer to being in a happy frame of mind than I remembered being for many years. Loss of memory was slight. The two main instances were that on my return home I was most pleasurably astonished to see my small son, and I had forgotten that I had a younger sister. It is remarkable how the appearance of a person one has forgotten as a result of ECT seems almost miraculous something created that instant, yet the person and all the circumstances return fully to consciousness at once. My own experience was that the memories lost returned with a pleasurable emotional tone. I have wondered whether this memory loss is somehow a reversal of the usual process whereby unpleasant memories are suppressed. An examination of the emotional tone accompanying returning memories might be illuminating. In my case no unpleasant memories returned in this special, sudden manner. The facts of my history carrying an unpleasant emotional tone (if I may so put it) were all present in my memory as before, but no longer seemed to have the power to drag me down into a depressed state.

I attended for a second treatment three days later. I felt very much greater apprehension and increased dislike of the whole thing. It had I imagine, progressed from the dentist's chair to the operating theatre in my estimation, though I have never been operated upon. As I had had no experience that could possibly justify that apprehension I did my best to dismiss it as irrational. I had however, formed the conclusion (on my own account) that the slight pain which had persisted since the first treatment was due to a strained back and a temporarily dislocated jaw. In spite of that I was puzzled to understand how an experience undergone during complete unconsciousness could lead to such apprehension. I was also astonished to have experienced the very striking certainty that something important and good had happened.

This attitude led me to decide on this occasion to close my eyes as soon as the electrodes were applied and concentrate upon trying to detect any sensation whatever between that moment and the time I should awake. My only experience was that, with my eyes completely but lightly closed, I did see one or two 'stars' moving gently. They were the kind of 'stars' one sees after a blow on the eye, but they drifted gently into view for an immeasurable instant and had no quality of violence whatever. They were not due to tight closing of the eyes as I had closed them only loosely. No muscular sensation whatever accompanied them. This time so far as I remember, my only loss of memory was that I did not dress completely before going to the rest room and I forgot that Dr X had asked me to see him before I left.

Subjective Effects

The most striking effect of these treatments on my behaviour and general attitude was that little routine duties and services to others, which had been a burden and even a cause for suppressed irritation, were now performed without the slightest hesitation and even with pleasure. My relations with my associates were made much more easy and natural.

I then within the next day or two, began to have symptoms which I identified as the physical reactions to fear. I still found this difficult to understand in view of the absence of any conscious experience of anything alarming. I had frequent and violent heart disturbance—a gross flutter or palpitation—and, what alarmed me much more, a kind of 'humming' or

fine tremor of the heart which I disliked extremely because I recalled some story or other which I had read years before about a madman who was troubled with a 'humming' in his chest. I also had for some days a mild but noticeable loosening of the bowels which I identified as similar to that occurring in some people when frightened. As a child and during the air raids I had experienced some heart flutter when excited, but I was not normally subject to the bowel effect.

I was also haunted by certain subjective experiences which I decided must be 'memory images' (my terminology). They were closely associated with the heart symptoms—i.e., when these images came to mind the heart trouble began, and I had to put them out of mind turn my head quickly and look at or think of something else for fear that if I continued to contemplate them the heart would get worse. These images were: (1) An explosive flash similar to one I had seen on the films of a mine being exploded *under water*. The water instantly goes white in a kind of aqueous flash radiating from the centre horizontally. It recalled the mine explosion because of its horizontal nature and its instantaneous spread in a liquid medium—as distinct from the less controlled explosion in air. (2) A somewhat similar image in many respects. In this case the memory was as if some flaky precipitate such as ground rice or soap flakes were at the bottom of a vessel of water. The flakes seemed suddenly and instantly separated vertically by a horizontal force through the water. They then settled down slowly through the water by their own weight until all was at rest again. (3) A flag attached to a flag pole, is suddenly and instantly stiffened as if by a powerful wind. These were not precisely seen but present as visually conceived ideas. I described them to Dr X who said similarly explosive ideas were frequent in ECT patients. (4) A fourth image of this nature but more easily understood was the figure of Dr X himself, standing beside the treatment couch as I had seen him at the moment of the first treatment. He was precisely as I had seen him but this image had for me the quality of the sinister dangerous professor in a thriller. Contemplation of it started the heart symptoms just as in the case of the others. I found it made not the slightest difference to my attitude towards him next time I saw him. But it might be well for the doctor to stand out of sight of a patient at this instant.

I have been much interested in the fact that these three memory images have all the same spatial quality. In each case the force is applied horizontally, and this is the case of course in the application of the treatment. I communicated all this to Dr X and attended at the clinic again. I felt that these symptoms were in some way a warning that further treatment might be dangerous. I was prepared to undergo further treatment if it were recommended and no doubt I would have been able to behave reasonably about it as before. I was, however, by no means confident of maintaining control against the really severe apprehension and the heart symptoms, which afflicted me even when waiting to see Dr X.

One other memory I could not get out of my head for some weeks. This was a genuine memory of the sound of the strange inhuman cry from other patients under treatment. Perhaps I am too sensitive but I think it might be well if steps were taken to deal with this. Although I knew it was an automatic expulsion of air and emotionally meaningless, it stuck constantly in my mind as a horrible thing.

In the event Dr X decided that it would be better to suspend treatment for the time being. He reassured me about my heart saying the symptoms would gradually pass off, which has been the case. Within two months of treatment I could not have written this without heart symptoms. The detailed recollection now has no such effect.

I have not been for further treatment because I am considerably improved and I hope it is not necessary. I am convinced that to complete the course might lead to further improvement but in the absence of the more distressing symptoms I formerly experienced I do not feel that the renewal of some weeks of such fundamental disturbance is worth while. I am advised otherwise I shall be willing to undergo further treatment but I hope to avoid it.

I have made no record of dreams and remember none, but I am sure I had some unusual dreams. One night I had a formless terror. It was causeless and I knew I was alone. I put on the light, sat up and waited until

it had passed and then went to sleep again. Another night I believe I had a slight muscular reproduction of the fit, or the sensation of it.

A most interesting effect of the treatment was that my imagination was very greatly stimulated. I soon began to write a fantastic Oriental fairy story with which I was, and am quite pleased. I had not previously done anything of the kind. I also took up work again on a book and completed about 60 000 words of it satisfactorily.

I suppose I am introverted. It is a fact that the treatment is felt as a threat to the secret inner world. I was most anxious about it. I knew that something I valued would be and was being destroyed. But might it not be a false value that I placed upon that inner world? I believe that it was a false value, otherwise, why should I awake from treatment with the certainty that something good had occurred?

THE BIRTH OF A BABY

The film entitled "The Birth of a Baby" has been classed by the London County Council as suitable for "A" exhibition and is soon to be shown to the public, at least in London, at one of the news theatres. A special showing of the film on June 11 was arranged by the National Baby Welfare Council, which is sponsoring the distribution of this American essay in adult education. The English commentary before and after the film proper points out the differences between American and English obstetrical technique and practice. It seems unfortunate, however, that during this commentary there should be only a succession of rather dull "stills" in strange contrast to the opulent setting of the film, particularly as it relates to the American family doctor. His equipment would be the envy of even a modern maternity hospital in this country. Despite these and other criticisms to which we drew attention when this film was first shown privately in London (*B.M.J.* 1940 1 264), the film has a real educational value. It contains nothing that would shock or unduly upset any normal young woman, and it presents in an easily assimilable form much of the detail of antenatal care preparatory to confinement at home. There are few doctors who will not be interested by it and there must be very few young married women who would not benefit by seeing it.

SPENS COMMITTEE FOR SPECIALISTS

INTERDEPARTMENTAL COMMITTEE OF INQUIRY

The Minister of Health, Mr Aneurin Bevan, and the Secretary of State for Scotland Mr Joseph Westwood, have appointed a committee of 11 members to recommend "what ought to be the range of total professional remuneration of registered medical practitioners engaged in the different branches of consultant or specialist practice in any publicly organized hospital and specialist service." The full terms of reference similar to those of the committee of which Sir Will Spens was chairman and which has recently submitted a report on the remuneration of general medical practitioners (Cmd 6180), are

'To consider after obtaining whatever information and evidence it thinks fit, what ought to be the range of total professional remuneration of registered medical practitioners engaged in the different branches of consultant or specialist practice in any publicly organized hospital and specialist service, to consider this with due regard to what have been the financial expectations of consultant and specialist practice in the past, to the financial expectations in other branches of medical practice, to the necessary postgraduate training and qualifications required and to the desirability of maintaining the proper social and economic status of specialist practice and its power to attract a suitable type of recruit, having regard to other forms of medical practice, and to make recommendations.'

The committee comprises Sir Will Spens CBE (Chairman), C R Dale, Esq., Sir Thomas Gardiner, GBE, KCB, T Lister, Esq. M.A., Miss Elizabeth Looker OBE, BA, Prof D Murray Lyon OBE MD FRCP Ed, FRSEd, Lord Moran of Manton MC MD, PRCP, Leslie E Peppiatt, Esq., Prof Harry Platt MD, MS., FRCS, S Cochrane Shanks Esq., MD FRCP FFR, J R H Turton Esq., MB FRCS, Mr T B Williamson, Ministry of Health, and Dr D P Stevenson, MRCS, L.R.C.P., Assistant Secretary, British Medical Association, are Joint Secretaries.

Reports of Societies

ERYTHROBLASTOSIS

Dr LOUIS K. DIAMOND of Harvard addressed the Section of Paediatrics of the Royal Society of Medicine on May 23 on erythroblastosis or haemolytic anaemia of the newborn. There was an erroneous impression, he said that this was a new condition of recent origin but it was well described in English literature before 1900 the pathology was fully illustrated by German investigators in the early part of the twentieth century, in 1932 at Harvard records of 20 infants manifesting a single underlying morbid process of erythroblastosis were published, and in more recent years much had been written on the Rh factor.

Problems of Rh Incompatibility

The Rh factor was considered to be positive in 85-87% of the white population of the United States, in 95% of negroes, and in 99% of Chinese. An investigation of 2,500 American ex Service men showed that more than 5% were Rh-negative and on receiving the Rh factor by transfusion developed antibodies. The danger of sensitization was much more than theoretical and must be borne in mind when giving transfusions. It was essential that no childbearing woman be given a transfusion until it was first determined whether she was Rh negative and might or might not have Rh antibodies.

In discussing sensitization during pregnancy Dr Diamond dealt with the effect on the progeny of an Rh positive father and an Rh negative mother. If the father was homozygous the children would be Rh positive and each of them potentially might be a means of sensitizing the mother if the father was heterozygous, half the children might be Rh negative and there was less danger. In addition it must be assumed that the placental barrier might be faulty and some foetal red cells might cross over and enter the mother's circulation. The first pregnancy was likely to be the least affected, because the mother was undergoing slow sensitization during that time it was in later pregnancies that the effect was more pronounced. One mode of sensitization which had not been appreciated until a number of cases of this sort had happened resulted in about half a dozen women from one particular clinic in their first pregnancy having babies with erythroblastosis. On investigation it was found that at this clinic it was customary to give intramuscular injections of blood as a means of curing vomiting during pregnancy. In the control of haemorrhagic disease in the newborn therefore it was important to refrain from using intramuscular blood until it was ascertained that the recipient was not Rh negative.

It was important, Dr Diamond continued not only to determine the Rh type of every recipient of blood and of every woman during childbearing but to follow the sensitizing process and to test the husband's blood and if possible to ascertain its homozygous or heterozygous quality. One other practical consideration was that obstetricians should be forewarned of the need to exercise great care before using the husband as a donor for transfusion to the wife. Every woman should be typed during the antenatal period the husband and children should be typed if the woman had been found sensitive and again in special cases, the woman's serum should be searched for abnormal agglutinins. There was always the possibility of a woman being sensitized to the factors in her husband's blood which she herself lacked.

Clinical Problems

With regard to clinical problems to be faced by the paediatrician about 20 years ago the blood of the father was generally used for transfusions and many transfusions were necessary because the red blood cells did not seem to survive as expected. The majority of children recovered, however, especially if there were no complications such as severe jaundice or cardiac failure. There were certain complications of erythroblastosis which were frequently called to the attention of the paediatrician. First there was the brain damage which occurred. In his series of children who survived some showed damage to their

higher centres and muscle control, but a fair number had shown relatively little disturbance later in life. The prognosis must be guarded in all cases. One complication less serious, but alarming to parents was the heavy staining of the tissues of the infant with the pigment present in jaundice. This pigment might be deposited in the teeth which were being formed at birth and later so that they took a green or greyish green colour. The parents might be assured that the permanent teeth would be normal in appearance. Changes were not observed in the bones with any frequency and most of the children who had not suffered nerve damage would survive.

Up to 1941, before the Rh factor was recognized, transfusion was given in an arbitrary way. Afterwards Rh negative blood was used, given frequently in small transfusions, and whether because of this or because the cases were recognized earlier the mortality dropped during the next few years from 40% to 30% among newborn infants. Then, it being a frequent experience that a normal infant at birth developed trouble later on, an investigation was made and it was found that in most of such babies at birth there was a certain amount of circulating antibody. Thereupon the practice developed, in addition to the transfusion, of delivering these babies two or three weeks before term, and the result of this was a further decrease in mortality. In a series of 350 cases the mortality dropped to 20%. Finally, still another improvement in therapy was effected. This was made possible by the development of a plastic catheter in the umbilical vein of the newborn infant by means of which constant withdrawal and replacement was possible. The infant's blood could gradually be replaced so that at the end about 80% of the infant's red cells and serum had been removed. The child was kept warm throughout the procedure, and oxygen could be administered. Relatively little difficulty was found in using this plastic catheter. This technique together with the earlier delivery was employed from January to July, 1946 in 15 severe cases, of which 9 died and, with an improved technique, from August 1946, to February, 1947 in 20 severe cases, of which only 3 died. Among 36 moderate or mild cases there had been only 3 deaths.

Dr Diamond recapitulated the improvement in mortality following advances in treatment as up to 1941, simple transfusions from father 40% mortality in 1942-4 transfusions of Rh-negative blood, 30% mortality, in 1944-6 the same plus delivery before term, 20% mortality in 1946-7, early delivery plus replacement transfusion—the present treatment—10% mortality. Of the babies who had died some had succumbed to the consequences of immaturity. Finally, he said that more study was needed before the problem of the management of blood incompatibility and antibody action between mother and child was solved. There was no justification for complacency in this field, neither was there any reason for undue anxiety when the problems of Rh incompatibility had to be faced.

At a meeting of the North of England Obstetrical and Gynaecological Society in Manchester on April 18 Dr VINCENT CORBETT described a case of vesico uterine fistula causing symptoms in a woman whose youngest child was 10 years old. The aetiology was obscure but it was suggested that the fistula might have been made by an attempt to cause abortion. Dr VAUGHAN JONES described two unusual cases of secondary post partum haemorrhage. Dr R. E. NEWTON described a case in which supravaginal hysterectomy showed a true placenta accreta in a fundal accretion which had ruptured. Dr J. W. A. HUNTER described three cases of carcinoma of the uterus appearing twelve or more years after the treatment of menopausal menorrhagia with radium. Mr PERCY MALPAS read a note on Smellie's method of forceps traction.

The Morgan W. Williams Bequest is a fund from which grants are awarded to medical practitioners and others ordinarily resident in Glamorganshire. The grants are intended to assist those wishing to travel abroad on short visits of medical interest. It is a condition of any award that the person to whom the grant is made shall forward to the secretary of the Welsh National School of Medicine a report on his visit. Applications for grants which should if possible be made at least three months before the proposed travelling date should be sent to the Secretary, The Welsh National School of Medicine, 10, The Parade, Cardiff.

Correspondence

Physical Therapy of Mental Disorder

SIR—By showing so clearly that even a psycho analyst has his blind spots, his prejudices, and his ignorances, by descending to the level of invective, and by upholding the 'right' of psychological science against the 'wrong' of physically orientated therapy, Dr D W Winnicott (May 17, p 688) has implicitly declared to us that, even in the name of positive science it is indeed difficult to get away from the evaluative statement. He can never free himself from making such statements as 'the wrong kind of doctor, skilled in the wrong way', 'depression is the illness of valuable people,' and 'I think leucotomy is the worst honest error in the history of medical practice'. He deplores, condemns, is shocked and horrified and he points the accusing finger. His statement that 'scientists hate empiricism and regard it as a stimulus to research' which I cannot believe he means, is the kind of slip of the pen which we can safely leave Dr Winnicott to sort out with his unconscious.

The notion upon which his whole argument seems to rest is that magic and science are irreconcilable, wholly alien to each other. It is upon this point rather than upon the specific issue of physical therapy in mental disorder, that I should like to join issue with him. It should be clear enough that when Dr Winnicott refers to 'magic' it is with an associated feeling of hostility while his references to science are those of a proponent. He loves science because he is dedicated to it. He holds to the one and eschews the other. Now it seems to me that it is this fundamental division of all experience into the 'good' and 'bad' the 'accepted' and the 'rejected' which is not only the origin of all evaluative judgments but is in Dr Winnicott's own case the underlying process in his prejudiced attack. Furthermore, it would seem that, in calling magic 'bad' and science 'good' he is doing no more than reversing traditional custom. In psycho-analytical language he is replacing a traditional worn out super-ego with his own 1947 model. He arrogates to himself the function of Inquisitor and with zeal pursues the misguided leucotomist in true heresy-burning fashion. He magically invokes science to condemn magic. The condemnation of a practice as immoral (in this case leucotomy and ECT) which issues from a philosophy that implicitly denies morality (in so far as it is positive and non-evaluative) is an absurdity. Dr Winnicott in descending from his Olympian perch and engaging in the humdrum squabbles of mortals cannot except by most serpentine logic, retain his Olympian status. He cannot be a referee in his own fight, but this appears to be what he is trying to do, and I must draw his attention to it. As to his personal opinions, however prejudiced they may be he is entitled to our respect, but his authoritarian attitudes deserve another fate—I am, etc.,

W MALCOLM MILLAR.

Gross, W, and others) When prefrontal leucotomy is given to the most hopelessly ill patients in mental hospitals, one out of three becomes well enough to return home, while 30% are much improved. Brody and others have been unable to find any intellectual deterioration as a result of the operation.

In view of the long and painstaking scientific research which has made these results possible (and they represent a vast alleviation of human suffering) it is difficult to understand why Dr Winnicott can describe these treatments as "brutal," or why he says that it is better to do nothing than to use them. Perhaps the reason why he has been misled is because it is well known that serious psychological symptoms in the case of children can clear up in a remarkable manner as the result of psychotherapy and even in some cases merely by lapse of time. It would be wrong however to suppose that the same applies to adults, and especially middle aged adults, who are most frequently the objects of shock treatments. The best analysts are careful to select their patients, and even Freud admitted that his methods were not successful with elderly patients or with psychotic patients. It would therefore seem illogical for Dr Winnicott to dissuade such persons from having any treatment at all. He evidently supposes that because a mental conflict has been a causative factor in the onset of an illness, the patient should be treated solely by psychological methods. It would be just as reasonable to forbid a patient suffering from Graves's disease to have an operation on the ground that emotional conflict was a factor in its causation.

When Dr Winnicott regrets that psychiatrists are as interested in biochemistry and neurology as in psychology he appears to be guided by a mistaken belief in the unreal Cartesian dualism of mind and body. For the psychiatrist however, the patient's organism must be considered as a mind-body unity and must be treated by psychotherapy and physical means as the situation demands. If Dr Winnicott were right, the psychiatrist would need no medical knowledge whatever. It is not true to say that no doctor would agree to have shock treatment. More than one has personally testified in the medical Press to the efficacy of ECT for melancholia while three research workers to my knowledge have submitted to a number of shocks in order to test the effects of different wave forms. One of these described the subsequent sensation as "like having drunk two glasses of champagne."

It is difficult to understand Dr Winnicott's prejudices, considering that so few patients dislike the treatment, while those who do are easily anaesthetized beforehand with a little "pentothal." Serious results may however follow from an attack of that character by a man of Dr Winnicott's standing for the patient may be denied the only form of treatment which will save him many months, or even years, of suffering in a mental hospital—I am, etc.

Shelton, P. (1942) *J Missouri State Med Ass* 39 53

SIR—Dr D W Winnicott's attack (May 17 p 688) on Physical Therapy of Mental Disorder merits some comment. Dr Winnicott is a paediatrician and a Freudian child psychiatrist and cannot therefore have had much personal experience of these methods. Before one dismisses so lightly these important developments in psychiatry as Dr Winnicott does one should first examine the actual results of these treatments. When ECT is used in cases of involutional depression figures of from 70 to 90% of recoveries are constantly reported (Sargant and Slater 1944) while hospitalization is reduced in cases of depression from an average of 63 weeks to 6 weeks (Sargant 1942). With regard to the insulin coma treatment of depression a statistical investigation in New York has shown that Governor Dewey has made it a successful State hospital. It was calculated that each case required 14 months hospitalization through the use of insulin and German investigations show that the mortality rate in insulin treated cases is in the order of 2.1 (Freudenberg, R. K. Sargant, W., Mav-

SIR—The inspiring and stimulating article by Dr D W Winnicott (May 17, p 688) shines like a beacon of light in the dark wilderness. I would like to write constructively further to my previous letters which I am given to understand have received a not inconsiderable measure of support. It is my view that it is quite unnecessary to be a doctor in order to give good psychiatric treatment. The important desideratum is to have people who by their characters deep culture and infinite patience are best fitted to undertake treatment in this dangerous subject. A psychiatrist does not always possess these attributes in fact there are many lay people who with a course of training in normal and abnormal psychology would make much better therapists. There are some distinguished psychiatrists and some good ones, but unfortunately they are in the minority.

I am in whole-hearted agreement with Dr Winnicott in his views against ECT. As regards the operation of prefrontal leucotomy which I witnessed many years ago as one of the first to be done in this country, it is one of the most dreadful operations I have ever witnessed, and I can pay

tribute only to the skill of the surgeon and to nothing else, but I would suggest that it is fundamentally wrong to operate grossly on the brain for conditions we do not understand and which may have a spiritual background and are far beyond our knowledge. Perhaps one of our psychiatrists would volunteer for the operation if it is contended that it does no harm.

I venture to prophesy that many of these modern treatments will gradually fall into comparative decay and will be used only in a selected one fifth of the cases in which they are now used. Psychiatrists must get out of the habit of trying to fit every single action of a patient, whatever it may be, into a pet pattern and jargon of their own, they would still somehow or other fit in these actions if the patient acted in exactly the opposite way. A perusal of some of their reports amounts to nothing more than a schoolboy copy of half a page of a textbook. After all, to a great extent psychology is only "informed" common sense.

The admirable and most instructive book by Dr C P Blacker on *Neurosis and the Mental Health Services* London, 1946 deals emphatically with this as the most important problem—namely, the proper selection of a psychiatrist. It tries to deal with all the difficulties of the situation from a short and long term policy. If an investigation is undertaken piecemeal in this way it will fail. What is needed is a commission of inquiry into every aspect of the case. It is absurd for psychiatrists to inquire into their own system and faults. The inquiry should be conducted by responsible and distinguished people into the mental hospital system and conditions therein, the selection and training of psychiatrists, the drastic curbing of their powers, the Chancery laws, the certification laws, the rehabilitation of the patient and the substitution of a greatly increased social medical service in place of much that now goes under the heading of psychiatry. They are in danger of being regarded in many cases as a menace and in other cases as a source of amusement. These are the views of an ever increasing number of doctors, and there are rumblings of more than discontent in the public mind which the real leaders of psychiatry would do well to heed in good time. I have myself drawn up a memorandum which I hope might be of some use to a commission of inquiry.

I would like to ask, say, twenty psychiatrists to undergo a course of ECT in order to record their own impressions. We should learn a lot from this. Let it not be said that their motto is "Do as I say and not as I do." Of all people as far as is humanly possible they should be beyond reproach. The name itself "psychiatrist" should be changed as it conveys a false and mystic sense of importance to the lay public.

In the past, and in a few exceptional cases, there was some brutality in some mental hospitals. The explanation by Dr Winnicott of this brutality is most interesting and as far as I know quite new, but how then would Dr Winnicott explain the subconscious motives of a few doctors who winked at what happened? I know of one case where an intelligent and educated person was wrongly placed in what is euphemistically called an observation ward. Here he was so treated that it is a wonder that he never went completely out of his senses. No theories can explain away such facts. Yet there is no remedy in law for this procedure, for the financial loss, the misery and suffering caused to the patient and his family, and for the after-effects. All the participants in such a case will find it very easy to play the victim off in order to ease their subconscious guilt feelings, but will not face up to facts and do justice, albeit at a very late stage, to the victim by adopting the obvious and comparatively simple way out. The injured patient should remain for always among his friends, it would be fatal for him to leave them.

It is interesting to note in the same issue of the *Journal* a memorandum on threatened suicide (*Supplement* May 17, p 103). What an anti climax to have to reiterate at this late stage that mental trouble may be a disorder of the emotions and not of the intellect.

The most important sentence in my opinion in Dr Winnicott's article so wonderfully expressed and which is the kernel of rehabilitation, is when he says that massed guilt feelings and hate and fear are aroused in people who are concerned with mentally ill people. I would like to add to this wonderful sentence, which may have far reaching consequences that the more supposedly mentally ill people defend themselves and their rights the more guilt is aroused in the people they meet in order to hide their own subconscious aggressive feelings and hate and guilt. If this question can be dealt with properly a great deal will be done to prevent the perpetuation of the condition of an innocent patient once falsely labelled. The patient or victim, as always comes first, and the desires of interested parties in many particular instances to whom often the patient's breakdown is almost entirely due and in other cases was deliberately fostered by them, should be recognized as being concerned with their own position alone.

Just as Dr Winnicott admits his prejudice in certain matters so I admit mine in others, but this is no reason why the facts I have given should not be correct. I am deeply grateful to Dr Winnicott for what I consider to be a momentous article, and I would like to pay tribute to the good work that is done by the right type of psychiatrist—I am, etc.,

London NW 11

A LIONEL ROWSON

SIR—I am interested in the correspondence on this subject and do not hesitate to express my views that there are patients who do benefit from ECT, leucotomy, and other physical forms of treatment, but there are those for whom I am certain that psychotherapy is the correct form of treatment. I must make a correction here that general paresis is an organic condition and would therefore be treated by organic methods (Dr G Tayleur Stockings, May 31, p 778). I appreciate that in making this statement I may be on uncertain ground as some research workers may be on the point of discovering an organic basis for the neuroses, but I know from my own experience and that of other analysts that patients can obtain a state of normality which they never knew in their lives before they were analysed, and this in the absence of any physical treatment.

I would not have been tempted to make this contribution had it not been that I have been unable to get what I consider adequate physical treatment for a patient I have under analysis. Briefly a severe obsessional male of 40 who lives 30 miles away was referred by his doctor in December 1946, for treatment. At that time he had pruritus ani for which no physical factor could be found. I took him on for analysis, but the severity of the pruritus soon prevented him from making the daily journey. As I had had fairly considerable experience of continuous narco-sis and skin conditions I advised his admission to a licensed house for this form of treatment. After a month he was relatively free from irritation and analysis resumed, until about 5 weeks ago when the pruritus again became painful, complicated by a general septic condition which put an end to travelling. He was willing to have further narco-sis, but not at the previous establishment, because he had found the quarters so uncomfortable.

I did not anticipate any difficulty in finding another licensed house where he could have this treatment, especially as it had proved its value for him before. We found another licensed house where his condition was diagnosed as a barbitone rash, continuous narco-sis was refused, and ECT made a condition of his continued residence, in spite of the fact that he had previously had it with disastrous results. I saw him after this experience, which had shaken his faith in psychiatrists still more. On account of his physical condition he was unable to make the daily journey to me, and I agreed to find a licensed house which would undertake narco-sis. This I did, explaining the position by telephone and to prevent any misconception followed this up with a report. He tackled his septic condition very well, but the whole question of continuous narco-sis has been evaded.

It is interesting to note that there are vogues for a particular brand of physical treatment, and it is impossible to obtain which is apparently outmoded however good it may be—I etc.,

Bishop's Stortford Herts

D N HARDCASTLE

SIR—I should like to join the doctors defending the physical methods in psychiatry against Dr D W Winnicott's point of view (May 17, p 688) with the simple statement I am convinced is right, that mental diseases *simul generis* do exist. I firmly believe that all mental disorders are symptoms of the acutely subacutely, or chronically ill physical organ called cerebrum. Without a physical dis-ease of the said organ—directly or indirectly—there are no "disturbances." *In corpore sano ad mens sana*. Those who believe in physical causes are nearer the truth and subse-quently nearer the solution of the great mystery of mental disorders than those who think that the philosophical psycho-theories are the last word in psychiatry. It is evolution psychiatry turns back to medical research seeking with the help of cerebral physiology and pathology the causes of mental disorders. It is refreshing to see the increasing number of doctors realizing this fact.

Till we know, ECT is under present circumstances one of the best if not the best treatment for shortening the time of hospitalization in a series of mental disorders, and what

PENICILLIN LOZENGES

(Troch. Penicil B.P.)

Penicillin Lozenges each contain 500 units of calcium penicillin and will retain their potency for at least six months at ordinary temperatures.

Indications—*Vincent's angina tonsillitis, streptococcal carriers and as a prophylactic before and after dental extractions.*

One lozenge should be placed in the buccal sulcus and allowed to dissolve slowly, when it is replaced by another.

E.S.T.P. - the improved Tar Preparation

BRAND (MARTINDALE)

Ether Soluble Tar Paste

Purified, decolorised, non staining, aromatic, maximum Tar effect

FORMULA

Ether Soluble Tar Distillate	15%
Zinc Oxide	14%
Starch	12%

In a special emollient base

A smooth paste easily applied. The tar component retains the essential phenolic compounds unimpaired ensuring powerful antiseptic action. All indications for Tar Treatment are indications for 'ESTP' (Martindale) more especially infantile eczema, eczema generally, impetigo complicating eczema, prurigo, pruritus, psoriasis, pityriasis circinata, lichen planus. In 2 oz and 16 oz pots. Sample and literature on request.

BELLADENAL

Antispasmodic .. Anticonvulsive
:: Sedative ::

BELLADENAL combines the central sedative action of phenobarbitone with the peripheral antispasmodic action of the total laevorotatory alkaloids (Bellafoline) of Belladonna leaves. Bellafoline is only half as toxic as atropine in doses which are therapeutically equivalent in their effect on the parasympathetic.

Each tablet of Belladenal contains

Bellafoline 0.00025 Gm (1/250 grain)
Phenobarbitone 0.05 Gm (3/4 grain)

The components of Belladenal act synergistically with each other so that a powerful antispasmodic and sedative effect is obtained with comparatively small doses.

ERNEST E FELDMESSER

Nicotinamide and Diabetes Mellitus

SIR—In the *Journal* of Feb 9, 1946 (p 218), you kindly published my results of massive nicotinamide therapy in diabetes mellitus. These investigations were prompted (as then described) by an original theory that diabetes mellitus was a vitamin deficiency disease, and when commencing 'experimentation' by using massive dosages of different vitamins I was unaware that work had previously been executed on nicotinamide and carbohydrate metabolism. I have since learnt that such investigations have been reported. After publication of my results I received an overwhelming amount of correspondence from interested colleagues all over the world (some themselves diabetics), who promised to report their results to me. This was indeed welcome in view of the fact that I wished to pursue the question more extensively and the number of diabetics under my care was rather small. I have since collected an imposing and interesting amount of data which I hope to publish at a later date.

I was therefore most interested in Dr H J Wade's results of nicotinic acid amide on the sugar tolerance curve in six cases of diabetes (March 27, p 414). Dr Wade asserts that my results prompted him to pursue this investigation further, but unfortunately he did not pursue it very far. His administration of nicotinamide was of too short duration and the numbers of cases lamentably small. This is regrettable in view of Wade's superb opportunities for exhaustive investigation (Dr Wade is in charge of the Diabetic Clinic at the Salford Hospital, Manchester).

The fact that some workers report poor or negative results with this therapy need cause no despondency. My theory is that nicotinamide "slogs" the remaining islets of Langerhans to greater insulin production but does not affect the sugar tolerance curve in itself. The beneficial results of nicotinamide depend upon the amount of functioning pancreatic tissue. If the pancreas is completely fibrosed or lamentably poor in islets of Langerhans, then the nicotinamide will have no effect irrespective of dosage or duration of dosage, because a general cannot exhort a non-existent army to greater endeavour. Should there be, however, a reasonable quantity of functioning pancreatic tissue, then varying good results will be obtained by means of the nicotinamide stimulating the remnant of secretory tissue to greater production. According to the amount of islet of Langerhans present so the results will vary.

I would suggest, therefore, that every diabetic be administered with massive doses of nicotinamide. Some will receive no benefit, whereas others, with more functioning pancreatic tissue will be able to partake of the joys of eating more liberally and extensively without constant insulin injections. I hope to publish more rather interesting data on this subject later, but meanwhile I shall be grateful if interested colleagues will send me their results—I am, etc.,

Poole

W GORDON

Folic Acid

SIR—Dr Cecil L Forde reports (May 24, p 740) the use of folic acid in a case of subacute combined degeneration which had in addition, the peripheral blood picture of pernicious anaemia. He reports that the blood picture "responded" to "intensive" liver therapy for three weeks, but that the nervous lesions are not affected. Folic acid was given and "in a few days" there was marked improvement in the neural condition. If this improvement continues on folic acid alone this case deserves a detailed report, for it is, to my knowledge, the only example in the literature of a case of subacute combined degeneration which has responded to folic acid therapy. It is reasonable to suggest however that the three weeks intensive liver treatment was the most likely cause of the improvement—nervous as well as haematological—in this case. It is an established fact that unless treatment of pernicious anaemia is adequate—i.e. red cell count of 5,000,000 per cmm or more, with a normal mean cell volume—subacute combined degeneration

may supervene. Such adequate treatment of pernicious anaemia is always possible in the uncomplicated case, and, unless full haematological details are given, the onset of, or the progression of, subacute combined degeneration in pernicious anaemia adequately treated with liver extract cannot be accepted.

The work of Spies in America and Davidson in this country—to mention but a few—has already made it clear that folic acid will not prevent the development of the neural complications of pernicious anaemia nor improve them if they are already present. Severely progressive subacute combined degeneration has been reported in many cases receiving intensive folic acid therapy. This is a matter of grave concern to the patient and the doctor.

Folic acid is still in the experimental stage. It is not adequate treatment in pernicious anaemia, for in only a handful of reported cases has folic acid restored and maintained a normal blood picture. Much more research is required for the establishment of the indications for folic acid therapy. Spies—and the manufacturers of folic acid—have already recommended that pernicious anaemia should not be treated by folic acid alone because of the danger of the onset of subacute combined degeneration in such cases treated with massive doses of folic acid. It is surprising that so far there has been lacking in British journals the warning that folic acid is inadequate for the routine treatment of pernicious anaemia. There is still no substitute for adequate liver therapy in this condition—I am, etc.,

Frodsham Cheshire

J G A MCSORLEY

Vitamin C Deficiency

SIR—In *The Russells in Bloomsbury* by G S Thomson, there is a passage referring to a treatise on scurvy circulated in 1665. "He [Dr Maynwaringe] was referring particularly to that disease [scurvy] and to nervous complaint or complaints which went by the name of melancholia or hysteria and were associated by Maynwaringe with the Scurvy," and later "The real root of the trouble lay in the quantity of salt meat eaten of necessity by both rich and poor." In the *Journal* of May 17 (p 679) Dr L I Hatherley reports a case of vitamin C deficiency lasting six years which, within half an hour of the injection of ascorbic acid, instead of being weak, apathetic, and apparently dying became alert, bright, and cheerful. Later a deficiency of vitamin P was thought to be present in addition. Many years ago at a meeting of the Royal Society of Medicine I heard an Arctic explorer quoted as saying that he only once had any trouble with scurvy, and that was when a party instead of shooting bears for food lived on tinned food found in a cache.

As a poor substitute for lightly cooked meat for the past few years I have prescribed black-currant puree in a number of cases suspected of vitamin C and P insufficiency and more especially recurrent subconjunctival haemorrhage. At present I have a case of intra ocular haemorrhage under treatment, as no other treatment has had any success. From clinical experience and the studying of numerous reports, etc., I suggest (1) that much of the present tiredness, ill-health, etc., is due to deficiency of vitamin C and P, (2) that more fresh meat should be on the ration, (3) tinned meat should not be included in the meat ration, as its position in our diet is misleading, (4) we are certainly being starved as with the present calories, sufficient or insufficient, the chance is remote of a sufficiency of vitamins being present—I am, etc.,

Southsea Hants

F C B GITTINGS

The Nation's Food

SIR—I find your "Medical Notes in Parliament" (May 31 p 790) most interesting, for it appears that in the House of Lords on May 22 Lord Addison proceeds to prove Dr Bicknell's statement to be true and anything but false, sloppy, or inaccurate. It seems generally agreed that the domestic rations yield 1,600 calories per day and that unless one is financially placed so that one can afford to eat in restaurants, the remaining 1,300 calories per day, which are necessary for normal health, have to be made up of bonus issues of sugar, jams, meat pies, sausages, and the sweets ration. Lord Addison states that if the total quantity of food going into consumption is divided

the total population it will show that each person gets 2 900 calories per day but of course this gives a wholly wrong interpretation of the facts since those who can eat in restaurants must consume more calories than those who cannot afford to do so

Many of my national health insurance patients cannot afford to purchase meals in restaurants and as Lord Cherwell has so wittily pointed out these unfortunate people will have to consume either 100 oz (2.8 kg) of fish, or 5 lb (2.2 kg) of potatoes or 200 oz (5.7 kg) of cabbage in order to make up a deficient 1,300 calories. This is a gargantuan task which is beyond the ability of any patient I have at the present moment—I am etc

Leves Sussex

E J S BARTHOLOPE

De Morgan's Spots

SIR—Since it is impossible to prove the exact nature of De Morgan's spots by experiment I venture to suggest that dialectic consideration supplies us with a plausible explanation of their occurrence. I believe I was justified in writing (*Med Pr* 1943, 210 219, and *Rare Diseases and some Debatable Subjects* 1946 London p 51) the following: 'They are apparently true benign neoplasms (minute capillary angiomas) and although some of them disappear by spontaneous involution (? thrombotic or atrophic closure of the supplying blood vessel) they tend on the whole to increase in number with the individual's age. I regard them as simple *mutational* tumours (rather than telangiectases) of the cutaneous capillaries

I can think of no other equally plausible explanation of their occurrence. They apparently illustrate only one type of common non-malignant mutation of somatic cells at the surface of the body, some other types doubtless contain pigment as the one did which was microscopically examined by Sir John Blund Sutton if indeed the pigment in that particular 'spot' was not due to a capillary rupture which led to involution

I certainly am not the first to have suggested this mutational explanation for various 'spots' which appear spontaneously on the surface of the body (cf allusion by Lockhart Mummery when discussing malignant mutations of somatic cells) but I believe that 'ruby spots' will come to be regarded as the most conspicuous illustrations of non-malignant mutations of somatic cells—I am etc

London W 1

F PARKES WEBER

SIR—The very careful and convincing paper on De Morgan's spots by Capt A R Murison Lieut J W Sutherland, and Flying Officer A M Williamson (May 10 p 634) is a final refutation of the idea that these spots have any connexion with cancer, and Dr Parkes Weber in his letter of May 24 has underlined this conclusion which I think is universally accepted. These spots are flattened circular lens-shaped islets of connective tissue lying in the thickness of the epithelial layer of the skin and slightly raising it above the level of the surrounding skin. Each of them has a narrow vascular pedicle, like the stalk of a mushroom, through which blood vessels reach it. Owing to lateral movements of the skin this pedicle is subject to frequent obstruction too temporary to be called strangulation, and capillary angiectasis consequently occurs in the spot which assumes its characteristic scarlet colour with a sharp well-defined margin. Gentle rotary pressure with a glass slide can be made to empty the dilated vessels and the colour disappears to return as soon as the pressure is released.

The invasion of epithelium by connective tissue is a reversal of the process which produces carcinoma. I have never known a malignant growth of any kind originate in one of these spots and they must be regarded as entirely benign and unimportant products of advancing years especially liable to appear in the region of the waist where the skin is subject to pressure and to lateral displacement—I am etc

W SAMPSON HANDLEY

Passive Immunization against Measles

SIR—It would appear from all reports that for children under five years old the gamma globulin fraction is the safest and most reliable method of obtaining passive immunization against measles an added advantage being the smallness of the dose when dealing with these small children. As far as I can ascertain the only material readily available for this purpose

(apart from the parent's whole blood) is convalescent measles serum. With this the dosage is rather bulky and there is the danger of the serum containing the isotherogenic agent of homologous serum jaundice. In this connexion I have heard that one or two deaths have occurred, and this has deterred me from using this substance. I should be grateful for an authoritative opinion as to whether this risk is such as to contraindicate the use of convalescent serum.

My main point in writing this letter, however, is to inquire why gamma globulin is not manufactured in this country, and if for some reason it cannot be manufactured, then why is it not imported? The substance must have been in use and favourably reported on for over two years, yet none of the local chemists can obtain it from the wholesale chemists, as it is apparently manufactured solely in America and is not being exported to this country. Surely, Sir, it would be of far more value, if it is a question of dollars to have gamma globulin rather than American brands of iron compounds, antacids, and the like of which we already have a surfeit of efficient English makes—I am, etc,

Acid Drinks and Sulphonamide Therapy

SIR—While agreeing that natural fruit acids are oxidized and cannot therefore be suspected of altering the blood acid-base ratio to the acid side I must protest at the illogical attitude taken regarding their administration during sulphonamide therapy. It is not enough to continue the fashion of prescribing fruit juice drinks on the lame excuse that they do no harm. It is abundantly evident from others as well as my own clinical experience that thorough alkalinization to the extent of rendering the urinary reaction alkaline is the surest method of obviating toxic reactions such as crystalluria, focal nephritis, haematuria, etc. The greatest risk of renal complications attaches to sulphapyridine, sulphadiazine, and sulphathiazole. At a urinary pH of 8 the solubility of these sulphonamides is approximately 2.2, 11, and 8.5 times as great as when urinary reaction is pH 5 to pH 6.

The obvious method of ensuring the necessary alkalinization of the patient is the liberal exhibition of easily assimilable alkalis in the form of sodium bicarbonate, carbonates, phosphates and citrates (where there is good tolerance to the last) in physiological proportion—I am, etc

Med Res Cncl War Memo No 10 1945 pp 12, 21 London

Local Penicillin and Endaural Cortical Mastoidectomy

SIR—Endaural mastoid surgery—i.e., mastoid surgery performed through incisions in and about the external auditory canal and meatus—is gaining in popularity. Advantages of the method as contrasted with the post-aural approach include less haemorrhage and post-operative pain, speedier convalescence, and almost complete absence of scarring. The exposure obtained is such as to permit uncovering of the lateral sinus and dura mater removal of the mastoid tip if desired, and complete extirpation of the mastoid cells in all except perhaps the most cellular mastoids.

In endaural cortical mastoidectomy as usually described a wedge of skin is excised at the posterior and superior aspects of the external auditory meatus, this 'window' is left open for post-operative drainage and heals in a few weeks. I have employed the following modification successfully in some dozen cases. The incision—which is extracanalicular—is made parallel to and a millimetre or two behind and above the posterior and superior borders of the external auditory meatus respectively, and upwards along the root of the helix for about 1 cm, the lower part of the incision is made down to bone the upper part down to temporal muscle. The periosteum over the mastoid process and posterior zygomatic root is elevated retractors placed and the bone operation performed as usual. The external auditory canal is not disturbed.

At the conclusion of the bone operation the cavity is filled with a paste of penicillin solution and serum or plasma powder as described elsewhere (Harpman J A, *Lancet* 1946 2 808). The incision is then closed with a few fine sutures and the external auditory canal concha, and fossa triangularis (the concavity behind the anterior part of the helix) are packed with ribbon gauze. The suture is removed in about one week and the pack omitted a few days later. The stenosis of the external auditory canal fre-

Recently observed after cortical mastoidectomy performed by the external aural route has not been found following this endaural technique. The lesion in the cases in question was acute or subacute mastoiditis, the ear drums and wounds were healed within a week of operation.

Convalescence appeared to be aided by pre- and post-operative systemic penicillin treatment—I am, etc.,

J A HARPMAN

Treatment of Acute Mastitis

SIR—From the beginning of August until the end of October I encountered twelve cases of acute mastitis in thirty two consecutive midwifery cases of which half were confined at the local maternity hospital. Cases showed evidence of acute inflammation of a breast from the 7th to the 21st day after confinement, local inflammation high fever, and rigors. All cases except two resolved without surgical interference with penicillin *cum* stilboestrol therapy 100 000 units twice daily and stilboestrol 1 mg orally t.i.d. 600 000 units was administered in nine cases, 1 000 000 in one case. In the two remaining cases evidence of abscess was evident on the 3rd day of treatment. Both were dealt with surgically and penicillin was continued until temperature and local condition indicated that inflammatory mischief was well controlled. These two received 1 000 000 units.

Occurring so late the infection was deemed to be not of haematogenous origin, while on the other hand careful investigation failed to reveal evidence of case-to-case infection. Moreover inquiry in domiciliary practice showed that cases were common in the district in the practices of different midwives. The contingency of the epidemic is therefore difficult to explain.

The following preventive treatment appears to have been successful as no case has occurred in my practice since it has been carried out as routine. The nipple is cleansed with warm normal saline and dried with sterile cotton wool. It is then smeared thinly over with fresh penicillin cream. I have great hopes that many cases of mastitis can successfully resume breast feeding after treatment has been successfully completed but so far I have failed to persuade any mother to make the attempt—I am, etc.,

Fraserburgh Aberdeenshire

J MACLEOD

Poisoning by "Lethane" Insecticide

SIR—In the article by Dr C V Harrison (May 24 p 722) the composition of lethane 384 special is given as "12.5% of lethane 384 (N butyl carbitol thiocyanate) 37.5% of lauryl thiocyanate, [etc]". So far as my information goes this is incorrect. I believe the composition to be (as stated in the paper by Prof Buxton and myself in the *Journal* of April 11, 1942 p 464) as follows: 12.5% N butyl carbitol thiocyanate (or, alternatively *beta* butoxy *beta*-thiocyano diethyl ether), 37.5% *beta*-thiocyanoethyl laurate 50% refined paraffin.

The main constituent (*beta*-thiocyanoethyl laurate) was not investigated by Cameron, G R, Doniger, C R and Hughes, A W M (1939) *J Path Bact* 49 363, but some data regarding its toxicity to mammals are given by Main R J, and Haag, H B (1942) *Industr Med* 11, 531. The M.L. doses found for intraperitoneal and subcutaneous injections to guinea-pigs and rats were 1.48 and 4.3 ml/kg. These figures fall into the range given for lauryl thiocyanate, and the error (if it be such) does not necessarily invalidate Dr Harrison's conclusions. Nevertheless it may be well to publish this correction unless he has information that the composition of lethane special has been changed—I am, etc.,

London W C 1

J R BUSVINE

"Tuberculous"

SIR—I should like to draw attention to the all too frequent and improper use of the word "tubercular" when "tuberculous" is what is really meant. "Tubercular" is a general term used to describe any condition characterized by rounded nodules—for instance a new growth—and exostoses might be described as tubercular in appearance when they are nodular. Tuberculous has a limited and special application: it is the adjective which should be used instead of "tubercular" to describe a condition due to tuberculosis. One should say a tuberculous (not a tubercular) lesion, a tuberculous (not a

tubercular) abscess, when it is intended to convey that these conditions are due to tuberculosis. The distinction may appear to be meticulous but precision in language makes for clarity of thought and exposition, and the reader of an article is entitled to expect this from the writer—I am, etc.,

J M HAMILL

Sir Joseph Barcroft and Drugs in Asphyxia

SIR—I am sorry that my paper on the use of drugs in asphyxia appeared by some means as a letter in the *Journal* (June 7, p 825). It was originally prepared for the use of a medical committee in I.C.I., and it was my intention before it appeared in print to preface it with a paragraph explaining the part that the late Sir Joseph Barcroft had in its composition. As it stands it might well be the theorizing of a medical scribbler. In fact it was the culmination of a correspondence over many years and it incorporated several alterations made by Sir Joseph himself. As the matter is one of great practical as well as theoretical importance I think it is only right that it should be known that my 'letter' had this authoritative backing. Sir Joseph's letter returning it (with the caveat that he would not personally like to be responsible for giving strychnine to infants) was one of the last he wrote, and I should like to take this opportunity of recording that his interest and help in the work of a general practitioner who did not happen to have been one of his pupils were as keen and as generous as in that of the many research workers who did have that privilege—I am, etc.,

W N LEAK

State Medical Service in New Zealand

SIR—In response to Sir William Fletcher Shaw's letter (May 31, p 782) I would point out that my quotation from Mr Porritt's article in *St Mary's Hospital Gazette* contained the whole of his comments on medical service. I must dissent from Sir William's description of *St Mary's Hospital Gazette* as "almost a private publication", Sir William will find a copy, I believe in every medical library. That Mr Porritt's article was not intended to be a private communication is perhaps shown by the introduction to the paragraph on medical services, which runs as follows:

This leads me to a few words on things medical in New Zealand. For ten years the country has had a partial State medical service and a dispassionate appraisal of this is perhaps not without interest at the present juncture in this country."

I would also point out that Mr Porritt as a native of New Zealand, would perhaps be in a better position than Sir William to appraise the present position in New Zealand as compared with that position when he left the country 23 years ago. But it so happens that Mr Porritt's conclusions to which Sir William takes exception are strongly fortified by a much fuller exposition furnished by Mr Douglas Robb in a recent little book, *Health Reform in New Zealand* sent to me for review. Mr Robb is a distinguished consulting surgeon a member of the Council of Auckland University College and of the New Zealand Medical Council. He criticizes the absence of arrangements for postgraduate teaching and research. He remarks that the 'impetus for introduction of the State service was a political one and the conception of the details of the service was almost 100% political—few medical men appear to have been consulted as such'. While recognizing the increased financial prosperity of general practitioners he states his belief that "the service has been accompanied by a steady demoralization of the profession". His sense of general dissatisfaction with the present medical position is summed up in his request to urge which is the real purpose of his book for "the appointment of a Health Service Commission to inquire into all the aspects of the subject with a view to plans for the future. This suggestion is of particular interest to me as I begged the Prime Minister in a Parliamentary Question (*Hansard* Jan 21 1941) to appoint a Royal Commission which would take evidence from all sections of the community concerned with the Health Service before any definite steps were taken which would revolutionize existing arrangements. This request was refused but was repeated later by the Negotiating Committee of the medical profession, and again refused—I am, etc.,

House of Commons

E GR

Ethics of Government's Advisers

SIR—Examples of interference at a distance with the general practitioners' recommendations regarding the diet of his patients have been published from time to time in the medical and lay Press. We have been assured by Government spokesmen that lay interference—i.e. refusal to grant extra items of diet by the local food office staff—may be overcome by reference of individual cases to the Ministry when each case will be examined by the Government's panel of medical experts, whose decision again taken at a distance is apparently irrevocable. It has also been pointed out that interference from a distance occurs in the provision of surgical corsets. Here the Board of Trade is the culprit in the first instance, and certain medical advisers of the Ministry of Health or the Department of Health for Scotland in the second.

Now it is a generally accepted ethical principle in our profession that we do not give opinions on other practitioners' cases unless we are invited to do so, and then only after examining the patient. It would appear therefore, that there is a *prima facie* case against these medical experts or advisers whatever they call themselves of unprofessional conduct. Unless of course the changing face of Britain with emphasis on the encouragement of dishonesty and immorality, has been accompanied by a corresponding change in the ethical standards so long and so rigidly upheld by the General Medical Council—I am etc.

Denham Bucks

EUSTACE SHIPMAN

POINTS FROM LETTERS

Wrong Use of Power

Dr ELSIE M CHUBB (Capetown) writes 'I was much impressed at the stencilled copies sent out during the ban on the weekly Press and was rather surprised at the lack of initiative shown by so many others who merely accepted it. The appearing of the truncated *B.M.J.* was a very valuable protest against wrong use of power by the Government.'

William Blake Psychologized

Dr E WEATHERHEAD (Southborough, Kent) writes 'I suggest that if poor Blake is to be psychologized, he should also be physiologized and "prithologized". Had he lived in these days he would certainly have been "hospitalized".'

A Demobilized Doctor

'M.D.' writes 'Anticipating the happy occasion next year of the jubilee of the R.A.M.C., may one suggest an additional small function for that body and its R.N. and R.A.F. counterparts? The very worthy appeal on behalf of needful families of deceased members and ex-members with which you deal in your current number may I think, be supplemented by one—not definitely of monetary aspect—on behalf of the ex-members themselves. It is one for a little help and advice to those of them who meet with difficulties in their search for civilian occupation after demobilization. A case in point is that of a man of 35 who after his long service, mostly abroad, did his hospital course and then got ill. General practice is barred because of poor health, but research work is avidly sought for by this earnest worker. He has failed to obtain such employment after many inquiries. Perhaps he is on the wrong line, and possibly one of your kind readers could set him right.'

Attempted Suicide

Dr W. H. BRYCE (St. Andrews) writes 'Referring to the article in the *Supplement* of May 17 (p. 103) on 'The Law Relating to Attempted Suicide' it may be of interest to know that in Scots law attempted suicide is not a crime *per se*.'

Experiments on Human Beings

Messrs L. G. TRIDGELL, P. SAUNDERS and H. GARLING (London, S.E.22) write 'Last Dr. Louise Fraser's letter published in your issue of May 31 (p. 785) should lead others to assume that all experiments on human beings are unethical. May we as three of some forty conscientious objectors who took part in several experiments for periods up to five years state that we were under no sort of external compulsion to participate nor having started were we compelled to continue any longer than we thought fit. We have as yet insufficient experience of what happens in jail.'

Obituary

NOAH MORRIS, M.D. F.R.C.P.

Noah Morris, Regius Professor of Materia Medica at Glasgow University since 1937, died in Glasgow on June 1 at the early age of 53. By his untimely death the Glasgow medical school has lost one of its outstanding personalities at the height of his achievements. A native of Glasgow, Prof. Morris graduated B.Sc. with special distinction in physiology in 1913, M.B. Ch.B. with honours in 1915, and for his M.D. thesis in 1921 he was awarded the Bellhouston Gold Medal. He also held the degree of D.Sc. and the D.P.H. He was elected a Fellow of the Royal College of Physicians of London in 1943, and had been a Fellow of the Royal Faculty of Physicians and Surgeons of Glasgow since 1921.

Morris had been interested in physiology and biochemistry since his early days, and after a period as assistant and later demonstrator in the department of physiology under the late Prof. D. Noel Paton he was appointed professor of physiology in the Anderson College of Medicine while at the same time carrying on a general practice. In 1928 he was offered and accepted the newly created University lectureship in pathological biochemistry with which was combined the post of biochemist to the Royal Hospital for Sick Children, Glasgow. Here he laid the foundations of his reputation as a teacher and investigator. He published many papers on metabolic problems, particularly with reference to disturbance in acid base balance and the metabolism of calcium, phosphorus and fat. He frequently read communications to the meetings of the Association of Physicians and the British Paediatric Association and at the same time he inspired much of the research done by the other members of the hospital staff.

Prof. Ralph Stockman, who died at the age of 85 only last year, had been appointed to the chair of materia medica in 1897. He resigned in 1936 and Dr Morris succeeded him as the Regius Professor of Materia Medica. In the years which have elapsed since then he has more than maintained the high traditions of the chair. This appointment also carried with it the post of physician in charge of medical wards at Stobhill General Hospital—an innovation at the time but one which rapidly proved itself. Gathering about him a band of young and enthusiastic workers, Morris built up a department which soon became noted for the high standard of its teaching and for the vigorous research which went on under his leadership. Not content with this, Morris also achieved a high reputation as an administrator, and during the past two years his onerous duties as convener of the Committee of Postgraduate Medical Education were undertaken with his customary energy and enthusiasm. Indeed it is only a few short weeks since he ceased work. Following an operation, his health seemed to improve, but the nature of his illness meant that his days were numbered, a fact which he faced with admirable courage.

As a colleague, Morris was characterized by his loyalty to his friends, his sound judgment and his honesty of purpose. Although accustomed to speak his mind freely, he had few, if any, enemies, and as a regular attendant at medical meetings he would always be found the centre of a jovial group discussing the events of the day. He was widely read and well informed, and the pleasure he got from these talks was more than equalled by the pleasure he gave to others. He was respected and loved by undergraduates. Not only was he a clear and forcible lecturer but he had a great sense of humour, which students were quick to appreciate.

Morris's life was cut short at a tragically early stage and we mourn his loss. He lived his life to the full and he died as one would have expected—courageously and without complaint. We extend our deepest sympathy to Mrs. Morris who shared with him his enthusiasm and was proud of the success he had achieved and to his son and daughter.

Sir Alexander Macgregor writes 'I trust you will allow me to pay a tribute to the memory of the late Prof. Morris, my old friend and adviser in municipal hospital affairs. His dual appointment to the university chair of materia medica and as a physician to Stobhill Hospital was a happy event in the

history of medicine in Glasgow, and he was happy in it, for he at once established himself as a teacher of his subject in the classroom and as an exponent of humanistic medicine in the wards of the hospital. In both spheres his intellect and his strength of character and of purpose gained for him an ascendancy and influence in local and national affairs to which few attain. But it was not on this account alone that he won the esteem and unbounded affection of his colleagues and students. It was well known to his friends that his supreme interest in life was in his fellow-men and in the interplay of personality, and I know that he would have liked this to be said of him. He made and retained friends in every walk of life, he made friends of his students and was content only with the best they had to give, watching over their progress through the university and in after life. In his work as a physician and scientist he was quick to seize every opportunity to advance his subject and to encourage and even constrain others to join in the search for truth infecting them with his own enthusiasm. I should acknowledge with gratitude Prof. Morris's services to public health and the deep interest he took in the relations between clinical and preventive medicine. I was constantly indebted to his wise advice on our city hospital problems before and during the war. Had he lived he would have played a prominent part in the new health service.

Medical Notes in Parliament

APPOINTED DAY

On June 9 Mr VIANI asked when it was intended to bring the rest of the National Insurance schemes and the English and Scottish National Health Service schemes into operation.

Mr AILIE replied. The preparatory work necessary to arrange the transition from existing schemes and agencies and to create the organization to operate the new provisions effectively is very heavy. Considerable progress has been made with these preparations despite great difficulties of staff and premises. The various schemes are closely linked up with each other and with proposals for completing the break-up of the Poor Law and providing a comprehensive scheme of national assistance standing behind the insurance provisions. The Government consider that there are compelling reasons in favour of bringing all these schemes into operation on the same date. They have reached the conclusion that by giving high priority to the legislation which it is hoped to introduce next session to complete the break up of the Poor Law this will be possible. On a consideration of all the factors involved they have decided that the best date for this purpose is July 5, 1948 which coincides with the end of the next contribution year for health, pensions, and unemployment insurance.

NATIONAL SERVICE BILL

The Second Reading of the National Service Bill was moved in the House of Lords on June 3 by Lord HALL. He said that for the period provided in the Bill some 200 000 men would regularly be called up for twelve months full time training, with reserve training covering a further period of four years. The main object of the Bill was to prevent war.

The Archbishop of York said the reduction of service from eighteen months to twelve would probably enlarge the number of recently conscripted men who had to serve in Germany. In the British Zone of Germany there were several million young women in excess of the number of men. Some of them because of the circumstances of the Hitler regime were over-sexed. Inquiries by the medical authorities would show the result of the temptations to which these boys were subjected. He pleaded that conscripts should be kept in England a considerable time before being sent to Germany. Temptation often took place in the first weeks.

Incidence of Venereal Disease

Lord MORAN doubted the wisdom of recruiting by compulsion or of leaving to soldiers the decision on the numbers required. The experience when they pressed for the demobilization of doctors did not encourage them to give the Army a blank cheque in this matter. The decision about conscription would really be made when they knew the real potentials of the atomic bomb and bacterial warfare. There were great risks in employing conscripts overseas. In September of last year, in

our Army in Japan, of every 1 000 men 228 had venereal disease. In another command alongside 600 out of 1 000 had venereal disease—more than half. In Germany at the same time the figure was 185 out of 1 000, in Austria and Italy 168 out of 1 000, and in Burma and Malaya 141 out of 1 000. The figure in the Middle East was 31 out of 1 000. The reason for that lower figure was that there was really no mixing between the Army and the civil population. Those figures might alter from time to time but were substantially the same now. The figure for the Army at home was 33 in every 1 000. That was very much higher than usual, it was generally in the neighbourhood of about 12. He was told that the figure for syphilis worked out at about 5 to 6 per 1 000 among the civil population. They had the same prevalence of venereal disease in 1919 after the first German war when similar conditions prevailed. Then the figure was 150 out of every 1 000 in the Army of the Rhine while in the American Army in September of that year of all the white American troops in Germany and France, 859 out of every 1 000 had venereal disease. He quoted from Volume XV of *Medical and Casualty Statistics*. Absence from home was the factor which led to this high incidence of venereal disease. The longer a conscript was away from home the higher rose the rate and incidence of the disease. These figures lent no support to the Prime Minister's idea that the Army was a people's university.

Lord NATHAN said he had been staggered by the figures of venereal disease given by Lord Moran. He suspected Lord Moran had taken the figures for treatments instead of those for cases. The highest figure for the United Kingdom forces for the third quarter of 1946 was 9.6 per 1 000 and the lowest was for the latest quarter 5.3 per 1 000. In the British Army on the Rhine the highest figure was the third quarter of 1946 44.6 per 1 000 and the lowest figure the last quarter 30 per 1 000. In the C.M.F. the largest figure was 39.5 per 1 000 in the second quarter of 1946 and 22.8 per 1 000 was the lowest figure—being the figure for the first quarter of 1947 based upon January and February only. In the M.E.F. the highest figure was 9.4 per 1 000 for both the second and third quarters of 1946 and the lowest was 4.1 per 1 000 for the first quarter of 1946. In S.E.A.L.F. the highest figure was 37.6 per 1 000 for the first quarter of 1946 and the lowest figure 31.2 per 1 000 for the first quarter of 1947, based upon January and February only.

Lord MORAN said he had quoted from A.M.D.5 Statistics, September, 1946. The figure of 228 per 1 000 which he had given had nothing to do with treatments. It meant 228 on an annual rate. These figures had been given officially by the Army Medical Department.

Lord NATHAN said there was no disagreement that venereal disease had to be dealt with properly and promptly. General McCreery, Commander in Chief of the British Army on the Rhine had devoted time and labour to put this right. But on the whole they must rely for conduct abroad on what these young men learnt at home.

The Bill was read a second time and referred to a Committee of the whole House.

SCOTTISH UNIVERSITIES

On June 3 Mr RANKIN discussed admissions to the Scottish Universities. He said that last November Mr DILTON stated that for the session 1945-6 there were 6 440 applications for admission to the four Scottish universities but that almost 50% of these candidates although equipped to benefit from a university education, had not been admitted. The raising of the school-leaving age would create a need for something like 15 000 new science teachers in secondary schools. This was a demand which the universities as a whole must meet. The number of students in Great Britain had risen by 32% since the war but in Scotland by only 28½%. Scotland ought to contribute 5 000 or 6 000 to the extra graduates required, but last year the number who graduated in pure or applied science from Scottish Universities was 460. When they added the numbers in medicine and arts it seemed clear that the obligations which would be placed upon Scotland would not be met. He suggested the solution of the problem lay in founding another university. Claims to this had been made from Dundee, Oban, and Dumfries but he favoured Inverness.

Mr GLENNIE HALL said Scotland was not alone in having crowded universities. Other universities were absolutely packed out because 90% of the places had to be reserved for ex-Service men and women. Scotland proposed to increase by 32% the places available for students raising them from 9 500 to 12 500 and the expectation was that she would be able to crowd in even another 2 000. There were limiting factors which would prevent the Government from initiating the building of another university. It could not undertake to find building labour or material nor would there be the teaching staff at the

present moment. Where buildings could be easily converted extra places could be found for students. Recurrent grants for all purposes given to universities were: Aberdeen £158,000, Edinburgh £255,200, Glasgow University £305,550, Glasgow Royal Technical College £37,000 and St. Andrews University, including Dundee £162,050. In addition capital grants for building and equipment had been allocated to a total of £172,100 and additional grants of £15,000 to Edinburgh and £80,000 to Glasgow had still to be approved. Grants to Scottish teaching hospitals attached to the universities amounted to £159,550 out of £500,000 allocated to this purpose.

Services Medical Examinations

Mr. HUGH FRASER asked on June 4 what steps the Minister of Defence was taking to bring the medical examination and documentation of all ranks of the British forces especially in regard to pulmonary and dental x-ray into line with modern practice in the U.S. and late German armed forces.

Mr. ALEXANDER replied that up to date methods were already used in all three Services. Medical examinations in the Navy included miniature radiography of the chest when a person was entered or as soon as practicable afterwards, and thenceforth periodically so far as staff and equipment allowed. A follow-up system included full scale films and special observation in hospital of doubtful cases. The number of dental x-ray machines had recently been considerably increased so that all essential x-ray examinations could now be carried out. Over 90% of Army recruits were examined by mass radiography to detect primarily the presence of pulmonary tuberculosis. As soon as enough staff and equipment were available all recruits would be so examined. Facilities were available for dental x-ray for diagnosis and treatment. In the Royal Air Force all recruits had a chest x-ray as a routine. Further chest x-rays, and also dental x-rays were arranged as required. The facilities would be developed further as and when skilled personnel became available. In general routine dental x-ray examination and documentation of all personnel was not regarded as justifiable having regard to the present resources of the country. An inter-Service Committee on medical documentation had recently been appointed to consider the possibility of introducing a common system for the three Services on the most up to date lines bearing in mind war experience not only in this country but also in Germany and the United States.

Medical Certificates

On June 5 Mr. JOHN MORRISON invited the Minister of Health to give a list of all the certificates required by Government Departments which a doctor may be called upon to sign on behalf of a patient.

Mr. BEVAN in reply said that according to his present information medical certificates may have to be produced by patients (or their personal representatives) to Government Departments under the following enactments or for the following purposes. This list was not necessarily exhaustive.

1 Under the Births and Deaths Registration Acts, 1836-1926, e.g., to certify cause of death to the registrar.

2 To assist in determining a claim to war pension or allowance.

3 Under the Lunacy and Mental Treatment Acts and the Mental Deficiency Acts.

4 In support of claims to benefit under the National Health Insurance Act, 1936, and the Contributory Pensions Acts, 1936-41.

5 In support of sick absence by a Government Department as employer.

6 Under the Blind Persons Acts, 1920 to 1938 to support an application for old age pension at 50.

7 Under the Essential Work Orders, Control of Employment (Directed Persons) Order, 1943 and Control of Engagement Orders in support of a claim to leave or change the employment.

8 Under the Road Haulage Wages Act, 1938, the Catering Wages Act, 1943 and the Wages Councils Act, 1945 in support of a permit to be employed at substandard wage rates.

9 Under the Coal Distribution Order, 1943 and the Control of Fuel (Restriction of Heating) Order, 1947 to obtain additional supplies of fuel and exemption from heating restrictions.

10 Under the Disabled Persons (Employment) Act, 1944, for registration.

11 Under the Corsets (Manufacture and Supply) (No. 14) Directions, 1946 to assist in obtaining surgical corsets.

12 Under the Welfare Foods Order, 1946, to enable expectant mothers to obtain food benefit.

13 Under the Rationing Orders or otherwise to enable invalids to obtain special authority for supplementary rationed food and to assist invalids, expectant mothers and others to

obtain special treatment with regard to goods which are the subject of Government control.

14 Under the Control of Motor Fuel Orders to assist claimants for additional petrol allowances on medical grounds.

15 Under the National Service Acts, 1939-47 in support of a claim for exemption from, and to justify failure to comply with provisions of the Acts.

16 Under the Cremation Act.

Rubella—Mr. HASTINGS on June 5 asked the Minister of Health whether, in view of the increasing birth rate and the clear evidence that German measles in the mother could produce serious defects in the unborn child, he would make this a notifiable disease, so that precautions could be taken to prevent its spread. Mr. BEVAN replied that the effects of this disease in pregnancy were being investigated in conjunction with the Medical Research Council. He preferred to await the results of this investigation before considering the matter further, and he invited Mr. Hastings to furnish his evidence.

Medico-Legal

A STERILIZED HUSBAND

[FROM OUR MEDICO LEGAL CORRESPONDENT]

We noted in our issue of Jan. 18 (p. 118) the decision of the High Court in *J v J*¹ rejecting the petition of a wife for a decree of nullity on the ground that just before the marriage her husband had himself sterilized by vasectomy. Mr. Justice Jones found that this act amounted to wilful refusal to consummate the marriage but he rejected the wife's petition on the ground of acquiescence: she had signed before marriage a statement that she fully understood and realized that the operation produced total and irremediable sterilization. The Court of Appeal has now reversed that decision and granted the wife's petition.

Lord Justice Somervell reading the judgment of the court, agreed with the judge's statement of the law but disagreed with his finding that the wife had acquiesced in the sterilization. The principle, he said, had been established by *Cowen v Cowen*² that a marriage was not consummated if a husband, by his own act in insisting on using a contraceptive prevented sexual intercourse from having its natural consequence. The husband in the present case had effected by an operation what could have been effected by the use of a contraceptive on each successive occasion. By his act in submitting to the operation he had rendered himself incapable of effecting consummation. When the couple had been engaged for some months the wife had refused to sign the statement required by the doctor as a condition of performing the operation. She had ultimately consented to sign on the husband's promise to postpone the operation until after the marriage, for she had hoped to be able to persuade him to a different view. In spite of his promise he had undergone the operation before the marriage and she had not known this until some six weeks before it. Her knowledge was not in law an absolute bar to her petition, and the question remained whether the petition should be dismissed in all the circumstances including her knowledge for lack of what was called "sincerity". The marriage had taken place in June, 1934, she had not known until late in 1945 that she might have grounds for a decree of nullity and she had then left her husband and filed her petition. Lapse of time was no bar until a party knew both the facts and his or her legal rights. The judge was wrong in dismissing the petition because of the wife's knowledge before marriage. That knowledge had not existed at the time of the engagement, it had been sprung on the wife a few weeks before the date of the marriage, and would not have been an easy reason for her to give for breaking off the marriage. She had felt that it was too late to draw back. In all the circumstances the court did not think that the petition should fail for "insincerity". The question of wilful refusal to consummate the marriage did not arise, the husband's incapacity was a sufficient reason for a decree of nullity, which the court pronounced.

* Includes primary form for England and Wales London (administrative county) and Northern Ireland

* Includes paratyphoid fever for England and Wales and Eire

Smallpox

Contacts are still under surveillance in connexion with the outbreaks at Barnsley C B, Bilston U D, and Coseley, U D. A first case in Wakefield C B was detected on June 4

Barnsley—There have now been 15 cases with 3 deaths in persons aged 75, 72, and 70 years. Of these cases 9 were in the second generation and 1 is probably in the third generation. The common lodging house where the disease first appeared and its occupants have been disinfected terminally but have remained under surveillance since the last case was removed on June 4. This man had refused vaccination until June 3.

St Helen's Hospital, from which the last case was removed on May 29, is now empty. Patients and staff from the affected ward have been transferred to a ward set aside for their reception at the Infectious Diseases Hospital. Other patients have been discharged home under surveillance and the hospital is now being disinfected.

The situation at Barnsley is reasonably satisfactory apart from two disquieting features. (1) A child aged 11 was admitted to St Helen's Hospital on the night of May 15 for tonsillectomy. Operation was postponed and she was discharged the following day. The parents refused vaccination. The child is said to have become ill on May 21 and developed smallpox rash on May 26. She was not removed from her home until May 29 and while ill in bed there received a number of visitors who are now under surveillance. (2) A man who had refused vaccination absconded from the common lodging-house and walked to Darton, a suburb of Barnsley. He returned to Barnsley by bus on May 29 and was removed to the smallpox hospital later that day. He says his rash appeared on May 28. Although many of his contacts have been traced some of them may not be under observation.

Bilston—Two further cases have been reported recently. The fourth member of the family mentioned last week (June 7 p. 831) was removed on June 2. She is 12 and was vaccinated in infancy and re-vaccinated unsuccessfully on May 17 the day after her sister died. Further re-vaccination on May 23 gave a good take, but she developed a modified smallpox rash on June 2 and was removed to hospital immediately. Her mother, another case in the same generation with onset on May 29, died on June 5. The second case, a teacher at Villier School, aged 39, was vaccinated in infancy and removed on June 4 (onset June 1, rash June 4) from a previously unaffected household.

Coseley—There have been no further cases in this district. Contacts in two households remain under surveillance and further cases if any should crop during the week ending June 14.

Wakefield—Here a man aged 71, vaccinated in infancy, became ill on May 31 and was removed on June 4. The date of the rash is uncertain but the clinical state suggests that it appeared about June 2. The man is one of 45 permanent residents in the model lodging-house 62, George Street Wakefield, but was employed as night watchman at the corporation's electricity works. There is evidence that no casual vagrants stayed at the lodging-house but passers-by frequently sat with him by his fire at work during the night.

Sheffield—The last of 3 cases (in two generations) was removed on May 21. Surveillance of contacts has now ceased and the patients are awaiting discharge.

Discussion of Table

In England and Wales there was a fall in the notifications of whooping-cough 241, diphtheria 46, scarlet fever 46, and dysentery 18. There was an increase in the incidence of measles 152.

The decline in the number of cases of whooping cough was produced by a few counties the largest falls being Yorkshire West Riding 92, Middlesex 48, Lancashire 42, London 37. The only changes of note in the returns for diphtheria were decreases in Durham 12 and Northumberland 10. The recent small rise in the incidence of diphtheria in Lancashire has increased the proportional importance of the returns of this county, and during the week one-third of the total notifications were recorded from Lancashire.

Only small changes occurred in the local returns of scarlet fever. The increase in the notifications of measles represents the balance of the conflicting trends. Increases were recorded in Essex 291, Yorkshire West Riding 208, Kent 191 and Worcestershire 137, there were decreases in Glamorganshire 201, Staffordshire 150, and Derbyshire 142. Lancashire had 16 and London 10 cases of dysentery. Cases of smallpox were recorded from Staffordshire, Bilston M B 1, Coseley U D 1, Lincoln

shire Grimsby CB 2 and Yorkshire West Riding Barnsley CB 3, Sheffield CB 1

In Scotland the only marked changes in the notifications of infectious diseases were decreases in measles 45 and whooping cough 35. In the Western Area a fall was recorded in the incidence of cerebrospinal fever 9, and of diphtheria 12.

In Eire the notifications of diphtheria increased by 13, while a fall occurred for scarlet fever 11 and whooping cough 13. The rise in cases of diphtheria was mainly due to an increase in Dublin CB.

In Northern Ireland the trends of the various infectious diseases remained practically unchanged.

Week Ending May 31

Notifications of infectious diseases in England and Wales during the week included scarlet fever 886 whooping cough 1 657 diphtheria 194 measles 12 314, acute pneumonia 512 cerebrospinal fever 3, dysentery 46 acute poliomyelitis 18 smallpox 14, paratyphoid 7, typhoid 1.

Medical News

The annual meeting of the Association of Surgeons of Great Britain and Ireland 45 Lincoln's Inn Fields, London, WC2 will be held at the School of Geography, Mansfield Road Oxford, on Thursday, Friday and Saturday July 3, 4, and 5. The programme is as follows: July 3 9.30 a.m. business meeting 10 a.m. discussion on 'The Surgical Relief of Pain (excluding Sciatica)' to be opened by Mr J. H. Keligren, Dr W. K. Livingston (USA), Prof J. Paterson Ross, and Prof Geoffrey Jefferson 12.30 p.m. short paper by Prof L. J. Witts 'Splenomegaly', 2.15 p.m. discussion on 'The Modern Treatment of Toxic Goitre', to be opened by Mr Geoffrey Keynes, Prof H. P. Himsforth, Mr T. A. Hindmarsh, and Dr Oliver Cope (USA), 4 p.m. short paper by Prof J. R. Leammonth 'The Results of Treatment of Traumatic Arteriovenous Fistula', July 4, discussion on 'Cancer of the Cardiac End of the Stomach and Lower End of the Oesophagus', to be opened by Mr P. R. Allison, Dr L. G. Blair, Mr T. Holmes Sellers, Mr Vernon Thompson, and Mr N. C. Tanner 2.15 p.m., operating sessions and case demonstrations at Radcliffe Infirmary, Wingfield Morris Orthopaedic Hospital, and Churchill Hospital, demonstrations of cine radiographic studies and experimental work in the Nuffield Institute for Medical Research, demonstrations in the Institute of Social Medicine 5.30 p.m. demonstration by Prof R. R. Macintosh, 'Anaesthesia Applied in Research', clinical pathological conference at Radcliffe Infirmary conducted by Dr A. H. T. Robb Smith July 5, 9.30 a.m., short papers on 'Anorectal Fistula' by Mr C. Naunton Morgan, Mr E. T. C. Milligan, Mr O. V. Lloyd Davies and Mr W. B. Gabriel, 12 noon, short paper by Prof H. J. Seddon and Mr D. M. Brooks 'Results of Nerve Grafting in the Extremities'.

A joint meeting of the British Association of Physical Medicine and the Physical Medicine Section of the Royal Society of Medicine will be held at 1 Wimpole Street, London, W, on Wednesday, June 18 at 4.30 p.m., when Dr P. Bauwens will read a paper on 'The Complex Behaviour of High Frequency Current in Simple Circuits'. At 6.30 p.m. the annual general meeting of the association will be held at the Royal College of Surgeons of England, Lincoln's Inn Fields, WC, and will be followed by a dinner at 7 for 7.30 p.m.

A meeting of the London Association of the Medical Women's Federation will be held at Queen Victoria Hospital, East Grinstead Sussex, to-day (Saturday June 14), at 3 p.m. when there will be a demonstration of methods of treatment in plastic surgery.

An international short wave congress will be held at Amsterdam in 1948 on July 19-24. Members of the Board are Dr W. Beaumont, London, Dr A. Gertz Stockholm, Prof Dr C. Guarini, Naples, Prof Dr D. Kobak, Chicago, Prof Dr W. Kowarschik, Vienna, Dr P. Liebesny, New York, Dr J. Meyer, Paris, Dr L. Rosa Budapest, Dr J. Saidman, Paris, Dr J. Samuels, Amsterdam, Prof Dr F. Schemmzky Innsbruck, Prof Dr E. Schliephake, Wurzburg. Those wishing to deliver lectures should communicate with the Secretary Weteringschans 73, Amsterdam, before April 15, 1948.

An International Cytological Association will be founded at the Cytological Congress to be held in Stockholm on July 10-17. It will be a section of the International Association for Biological Research which is affiliated to UNESCO.

The report of a conference on catering for the aged and infirm held on Jan 18 (*Journal* March 15, p. 348) under the chairmanship of Lord Amulree, has been printed as a pamphlet entitled *Nutritional Problems of Invalids the Aged and Infirm* price 1s (plus postage) obtainable from the London Council of Social Service, 7, Bayley Street, London, WC1.

The board of management of the Hospital for Sick Children Great Ormond Street London, WC, announces that in an endeavour to lessen the time spent waiting in the out-patient department, out-patients will be seen by members of the consulting medical and surgical staff only by appointment. Such appointments should, if possible, be made by a doctor acquainted with the case and preferably by letter. Patients who attend without introductions from a doctor will be examined in the receiving room and only when necessary referred to a member of the consulting medical or surgical staff. Patients will be seen by appointment between the hours of 9.30 a.m. and 12.30 p.m., except on Sundays. The hospital is open day and night for urgent cases.

The National Association for the Prevention of Tuberculosis has decided to offer six scholarships this year, open to doctors and other medical personnel throughout the British Colonial Empire. The successful holders will come to Britain for a period of six months or longer to study tuberculosis in its widest aspects—clinical, administrative, and social. The award will be divided as follows: (a) Two scholarships (value £120 each) to registered doctors in the Colonial Medical Service; (b) Two scholarships (value £100 each) to medical graduates of native medical schools in the British Colonies; (c) Two scholarships (value £80 each) to matrons, nurses, health visitors, or other members of colonial sanitary departments. The successful candidates will be eligible for lodging and training allowances from Colonial Government funds, and the details of their training during the tenure of the scholarship will be supervised by the N.A.P.T. Travelling expenses, purchase of books, and other incidental expenditure will be met by scholars out of their scholarship moneys. Applications should be made through the Colonial Medical Departments, who will forward them to the Colonial Office which will make recommendations to the Council of the N.A.P.T. An announcement of the method of sending in applications will be made shortly by the Colonial Office.

The King Edward's Hospital Fund for London proposes to offer in the summer a number of bursaries tenable at voluntary hospitals in London. *Hospital Administration*—Three junior bursaries of the value of £350 a year for men or women aged 20-30, and three senior bursaries without an age limit of the value of £600 a year. *Catering Officers*—Eight bursaries valued between £300 and £600 a year for men or women. *Domestic Administration*—Six bursaries for women at the rate of £250 a year, plus board and lodging. Inquiries should be addressed to the Secretary, King Edward's Hospital Fund for London, 10, Old Jewry, London, EC2.

In July a new monthly journal will be issued called *The Annals of the Royal College of Surgeons of England* containing reports and lectures which have been recently given in the College. It will also include a diary of the activities and lectures of the College and will be of interest not only to Fellows but also to Members. The annual subscription is 25s. post free, single numbers 2s. 6d., postage extra. Applications should be made to the Editor, The Annals of the Royal College of Surgeons of England, Royal College of Surgeons, Lincoln's Inn Fields London, WC2.

Lord Moran has been appointed Chairman of the Medical Advisory Board of the Alfred Eichholz Clinic, London, which is staffed by blind men and women—qualified physiotherapists trained by the National Institute for the Blind.

The Minister of Labour and National Service has nominated Mr G. P. Barnett, one of H.M. Deputy Chief Inspectors of Factories, to be Chief Inspector in succession to the late Mr H. E. Chastaney.

Dr Emyr Wyn Jones has been appointed Sheriff for Caernarvonshire for 1947.

Dr Thomas Munn Body has been appointed a Deputy Lieutenant in the North Riding of the County of York.

Dr J. M. Cure has been nominated a Member of the Council of Government of the Colony of Mauritius.

The submission of Form T 147 under the Public Health (Tuberculosis) Regulations, 1940, is no longer necessary for men born between 1916 and 1926, but is required only for those born in the years 1927-9.

Dr William Hartley Thompson, of Bradford, who died on Dec 30, 1946, left £55,616. Dr Walter Charles Aylward, of Tunbridge Wells, who died on Jan 29, left £15,300. Mrs Vivien Hennessey Ada Lloyd Laming Evans, widow of E. Laming Evans, CBE, FRCS, formerly of Oxley, left £30,781, the residue, after certain bequests, to the Royal College of Surgeons, England, for research in orthopaedic surgery. Dr Stanley Wyard, of Wimpole Street, W1, who died on Sept 29, 1946, left £14,234. Dr Charles Grant Pugh, formerly Medical Officer of Health for Southend, who died on Dec 19, 1946, left £23,850. Sir Arnold Lawson, the ophthalmic surgeon who died on Jan 19, left £65,078. Dr Charles Llewellyn Lander, of Maiden Newton, Dorset, and Plymouth, who died on Dec 25, 1946, left £35,934. Dr John Young, Bishop's Stortford, Herts., who died on Dec 20, 1946, left £21,913.

Rutin in Capillary fragility

Rutin is a crystalline glycoside obtained from the leaves and flowers of buckwheat. Recent reports attribute to Rutin the property of reducing capillary fragility when this is abnormally raised.

In our research laboratories a limited quantity has been isolated from buckwheat grown in this country and is available in the form of tablets.

Rutin A & H is suggested for administration in hæmorrhagic conditions due to increased capillary fragility or permeability, especially when this condition is associated with hypertension, nutritional deficiency or toxic effects of drugs.

Literature and price on application

RUTIN A & H

W. ALLEN & HANBURY LTD; LONDON, E.2

Are you
meeting
with cases
of
malnutrition
in your
practice?

One ounce of Hepamino will supply	
BIO-TIN	- the total daily requirement
PROTEIN	- one half the total daily requirement
NICOTINIC ACID	- twice
RIBOFLAVIN	- twice
PANTOTHENIC ACID	- three times
FOLIC ACID	- twice
ERYTHROXIN	- one quarter
INOSITOL	- one eighth

—and these are immediately available for biological utilization. Also present are iron and copper, vitamins B10 and B11, purine and pyrimidine bodies and anti-macrocytic anemia factors.

Erythropoietic Fraction of Liver

Clinical experience over a decade has established that the administration of Anahæmin B D H constitutes a most effective form of treatment of pernicious anaemia.

Anahæmin B D H produces, with small and comparatively infrequent doses, a prompt and satisfactory erythropoiesis in patients in relapse, it ensures the maintenance of a normal erythrocyte level in patients in remission and is effective in preventing the onset of subacute combined degeneration of the cord. Further information is available on request.

The Successful Treatment of FIBROSITIS and certain cases of RHEUMATISM with NOVUTOX

A mass of evidence has accumulated to show that the treatment of Fibrositis and certain cases of Rheumatism with Novutox injections provides not only complete restoration of function with immediate relief from pain but also, in many cases, early recovery

Interested members of the medical profession are invited to write for a copy of a Thesis on THE INJECTION TREATMENT OF FIBROSITIS—with special reference to Lumbago Muscular Rheumatism (Acute and Chronic) Muscular Pain (of Traumatic Origin)

NOVUTOX is available in

2-oz and 20-oz Bottles 1% 1% and 2% Solutions
Boxes of 12 x 2 c.c. Ampoules 1% and 2% Solutions

Each c.c. of Novutox 2% contains 0.02 gm ethocaine hcl 0.00002 gm epinephrine and 0.00002 gm capryl hydrocupreinatoxin hcl Other strengths of Novutox contain these elements (with or without epinephrine) in varying proportions

The Control of Bacterial Infection with

'SULPHAMEZATHINE'

'Sulphamezathine', officially known as Sulphadimethylpyrimidine B.P.C., is a dimethyl derivative of sulphadiazine and, like the parent substance, has a wide range of antibacterial activity. In addition it possesses a number of relative advantages which are of great clinical importance.

Noteworthy features of the administration of 'Sulphamezathine' are the almost complete absence of toxic after-effects and the rare occurrence of renal complications. The drug is rapidly absorbed and relatively slowly excreted, so that adequate blood levels are readily achieved and easily maintained by comparatively small doses.

In pneumonia, meningitis, haemolytic streptococcal infections and *Bact. coli* infections of the urinary tract treatment with 'Sulphamezathine' has proved particularly effective.

Powder Bottles of 25 grammes, 100 grammes and 500 grammes

2 tablets 0.5 gramme Bottles of 25, 100 and 500

Vitamin Therapy —its uses and limitations

SAFER PREGNANCY

Although priority supplies of essential foods are allocated to pregnant women, there still arise cases in which anaemia, fatigue, debility indicate to the physician that all nutritive factors are not, in fact, being assimilated at the level of their physiological requirement. Pregnavite is designed to contain, in a single preparation, those factors most likely to be needed and in doses such as to meet the requirements of most women.

PREGNAVITE

A single supplement for safer pregnancy

The recommended daily dose provides

vitamin A 4,000 i.u.	vitamin E 1 mg	iodine 1 mg	} not less than 10 p.p.m. in each
vitamin B ₁ 300 i.u.	nicotinamide 25 mg	manganese 1 mg	
vitamin B ₂ 0.6 mg	calcium 160 mg	copper 1 mg	
vitamin C 20 mg	iron 68 mg

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions. Questions should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Meat Extracts

Q—What is the nutritive value of the popular proprietary meat extracts? Is it possible to maintain life on them? Of what real value are they when included in an invalid diet? Also is there any truth in the popular theory that calf's foot jelly is very nutritious and strengthening?

A—It is understood that many of the proprietary brands of meat extracts contain besides the water-soluble extractives of meat, yeast extract and salt for flavouring purposes. Their nutritional value is to day rated rather differently from a few years ago, because of the discovery that they contain useful quantities of riboflavin and nicotinic acid. These may amount, respectively to averages of 1 and 30 mg per oz (28 g). Meat extracts contain about 20% each of water and mineral matter—presumably mostly phosphates and sodium chloride. Nothing appears to be known about the non-nitrogenous extractives, possibly they consist of soluble break-down products of glycogen. The nitrogenous extractives have been more fully studied. Peptones and similar compounds ("albumoses") amount to about 15% and are probably utilized as well as similarly constituted proteins, "meat bases"—creatine, creatinine, carnosine and anserine, glutathione, urea, and ammonia among others—make up the balance. These bases are believed to account for any effect meat extract may have in stimulating appetite.

Clearly these products, however great their value as adjuncts to invalid diets are in no sense complete foods. Even if enough could be eaten daily to provide the necessary protein equivalent—about 1 lb (454 g)—the deficiency in fat and carbohydrate, in vitamins A and C, and probably in calcium and iron is enough to put them outside any list of single foods that maintain life without supplement, incidentally there are no such foods. For fuller information a paper by Rees and Salway (*Chemistry and Industry* 1947, May 31, p 302) may be consulted. These authors make no reference to calf's foot jelly. Hutchison and Mottram regard it solely as a very expensive source of gelatin and say of "jellies" in general that their value to invalids probably depends on their content of sugar rather than of gelatin.

Production of Penicillin resistance

Q—Is there any danger of producing penicillin-resistant organisms in patients with acute infections of the mouth and throat treated with penicillin lozenges?

A—The capacity of bacteria to develop resistance to penicillin varies in different species. It is very great in *Staphylococcus aureus* and very small in *Streptococcus pyogenes* which is perhaps the most important organism likely to be subjected to the action of penicillin in the mouth and throat. It is also possessed in some degree by *Streptococcus viridans*. The plain answer to the question is "yes but the danger" to the patient himself is remote. The indiscriminate use of penicillin preparations of every kind which are easily and may be casually applied to parts of the body such as the skin or mouth which are heavily populated by bacteria is to be discouraged because such widespread abuse of a potent remedy continued for years may end in breeding widely distributed races of resistant bacteria.

"Susceptibility" to Lousiness

Q—There is a widespread belief that some persons are more susceptible to lousiness than others. While it is a fact that some people are more irritated than others by insect bites is there any justification for the view that the louse tends to select certain persons?

A—The writer has reared lice for laboratory experiments for several years and at different times has been assisted for

short periods by volunteers (about a score). On none of them did the lice show reluctance to feed. On the other hand, the hosts displayed a great difference in their reaction to bites, many being so severely affected that they were unable to continue. Among naturally infested people one finds great variation in the number of lice present, but in all cases the figure is not great (a dozen or so adults), and is much less than that which would be expected from the known powers of proliferation of the louse. Almost certainly this is due to the louse-killing activities of the infested people. Presumably this is partly dependent on their standards of hygiene but also on their sensitiveness. Individuals who suffer most would tolerate only very small numbers. In the case of fleas and mosquitoes, people who are sensitive are most likely to notice bites and therefore to consider themselves unduly sought after by the insects. With lice, however, it is the insensitive people who are apparently more "susceptible" to attack.

Smithwick's Operation for Hypertension

Q—To what extent is Smithwick's operation of lumbo-dorsal sympathectomy performed in this country for the treatment of hypertension? Is this procedure justified in a man, aged 45 with anginal attacks associated with hypertension but otherwise healthy?

A—Smithwick's operation (*Surgery* 1940, 7, 1) is a very extensive resection of the sympathetic system above and below the diaphragm, first on one side and subsequently on the other. This operation, or others of a similar nature but varying in extent, such as Adson's or Peet's operation, are being performed more frequently in Great Britain. Smithwick himself was able to give a review of a large series of his own cases over a period of five years (*Arch Surg* 1944, 49, 180), but no comparable series in this country has been published. Each case has to be considered on its merits after thorough investigation. In general in this country the operation is performed only on patients under 50 years of age who have systolic pressures over 200 mm and diastolic pressures over 100 mm who are deteriorating in spite of medical treatment, and who show little if any evidence of structural heart disease or renal disease. If the patient in question satisfies these criteria he should be investigated by the cold-pressor and sedation tests, so that the possible response to operative treatment may be gauged.

Chylous Ascites

Q—I recently operated on a woman of 25 for inguinal hernia. On opening the sac milky fluid tinged with pink, typical of chylous ascites escaped and some 12 oz (341 ml) was later removed from the peritoneal cavity. The patient had complained of no other symptom than slight pain in the hernial region. What are the aetiology and prognosis?

A—True chylous ascites is due either to injury or to obstruction of the thoracic duct (or receptaculum chyli) or of one of the more important intra-abdominal lymphatics, it is a rare condition apart from filariasis. Chyliform ascites is also uncommon but may be found in some cases of carcinomatosis, rarely in hepatic cirrhosis and occasionally in cases of tuberculous peritonitis. The last-mentioned is the more likely cause in this case, for it may occur unaccompanied by any other symptoms.

Premenstrual Mastalgia

Q—A woman aged 45 suffers from lumpy and tender breasts every three months or so—about a week before menstruation the condition subsides after her period. She fears cancer but is unwilling to have her breasts removed except as a last resort. Is stilboestrol worth trying? If so in what dosage? What other treatment would you recommend?

A—The occurrence of discomfort is so infrequent that it would be better to persuade the patient that no treatment other than a well-fitting brassiere is necessary. There is nearly always a large element of neurosis in "premenstrual mastalgia," and fear of cancer as in this case, is a common feature. Reassurance is therefore important. If the patient is not content with this general measures should be tried before endocrine therapy. The restriction of the intake of fluid and salt for ten days before a period is sometimes efficacious, small doses of thyroid also appear to help. Stilboestrol is used a good deal

in the treatment of this condition but the results are mostly unsatisfactory. If need be it might be given in 0.5 mg doses twice daily by mouth during the time when the discomfort is present. The more usual technique of using it during the first half of the cycle seems inappropriate in this case since the appearance of the pain is irregular. An alternative is methyl testosterone 5 mg sublingually twice daily for ten days before a period. Finally x-ray therapy should be considered.

Yohimbine

Q—What is the value of yohimbine? How is it given in what dosage and are there any contraindications to its use?

A—When yohimbine is given by mouth or hypodermically in moderate doses it produces a general vasodilatation in the skin the mucous membranes and particularly in the sexual organs in consequence it produces erection. It does not stimulate the production of spermatozoa or sexual desire. The effect is not produced by therapeutic doses in man (5 mg or 1/12 gr) although it has been recommended as an aphrodisiac. Large doses produce excitement cerebral congestion vertigo, and gastric disturbance. Yohimbine has also been proposed to lower abnormally high blood pressure but Lawrence found that it may produce a further rise with dangerous symptoms.

False Positive Pregnancy Reactions

Q—Assuming good technique is it possible to get a positive result from an Aschheim-Zondek or Friedman test in a woman known neither to have a chorion epithelioma nor to be pregnant? What are the conditions giving rise to this anomaly?

A—Yes a positive reaction is occasionally obtained in conditions in which there is overactivity of the anterior lobe of the pituitary. It is sometimes seen for instance when the pituitary is released from the normal inhibition of the ovary as at the menopause and in some cases of genital tuberculosis associated with metrorrhoea. It has also been described in association with pituitary disease (such as acromegaly) and tumours of the midbrain. The occasional finding of a positive Aschheim-Zondek reaction in cases of genital carcinoma is probably explained by the fact that the patients with such lesions are mostly of menopausal age.

Sore Tongue

Q—What are the probable cause and the treatment in a case of sore tongue in which the tongue is furred centrally and has marked injection of papillae at the tip extending about an inch (2.5 cm) along the edge and in which dental and blood disorders have been excluded also vitamin deficiency and all known and evident dietetic irritants?

A—It is difficult to offer constructive suggestions in this case, for the common extrinsic causes of soreness of the tongue have been excluded and the appearances described are not characteristic. Sore tongue is sometimes the complaint when the underlying abnormality is xerostomia—for instance in Sjögren's syndrome hysteria must not be forgotten. In the absence of a clear-cut diagnosis the only possible treatment is palliative avoidance of unduly hot or cold food and drink and of physical and chemical irritants such as seasonings and smoking and lubricant mouth-washes before meals in which 1% amethocaine hydrochloride may be included if the discomfort is severe.

Circumcision

Q—A patient with an exceptionally long but easily retracted foreskin desires a circumcision. Is the cuff method of operation satisfactory and would it enable the patient to carry on his normal sedentary duties without interruption?

A—The answer to this question depends on what is meant by the 'cuff' method of circumcision and on what are the precise reasons for operating. If by the 'cuff' method is meant the leaving of enough foreskin partially to cover the sensitive glans penis and if the patient wants redundant foreskin removed merely to facilitate penile hygiene this method should prove satisfactory. Discomfort after circumcision is in great part due to post-operative infection and this can be reduced by the use of a penicillin cream as a dressing. In any case the interruption to his sedentary duties should be but a short one.

Letters and Notes

Raven's Intelligence Test

Mr JOHN C RAVEN (Dumfries) writes: May I draw attention to certain matters on which the person who answered the question 'Is Raven's test—the progressive matrices—satisfactory for estimating general intelligence?' was ill informed (May 17, p 706). 'Progressive matrices' (1938) was never intended to be a test of 'general intelligence'. It was designed to assess a person's output of intellectual activity at the time of the test, and has proved to be the best test for this purpose yet produced. Only under certain circumstances does the so-called 'K' factor affect the results obtained. There is no reason to assume that a person's output of intellectual activity is always the same. Data obtained with the matrices test indicate that it varies considerably in health and illness. This does not mean that the test is unreliable. Success in the test does not depend upon acquired knowledge. For this reason it is one of the most valuable tests for distinguishing backwardness due to loss of schooling from genuine mental deficiency. Adults' scores on the test decline with age. The fact that other tests fail to show this does not mean that they are better tests. It is often more difficult to answer questions than it is to ask them. Many readers of the *Journal* will I think, be glad to hear that a book dealing with 'The Assessment of Mental Development' is nearing completion, that an inquiry into variations in the intellectual activities of adults in health and illness is in hand and that three derivatives of progressive matrices designed for use with little children, with adults and with adults above average in intellectual capacity, have just been completed.

Tinnitus

R writes: The question and answer on the subject of tinnitus (May 17 p 706) revives memories of my first weeks in practice when I was in the habit of giving maximum doses of all tinctures. An old lady consulted me about tinnitus from which she had suffered for years, and forgetting that the dose of tincture ofaconite was 2-5 min (0.12-0.3 ml) I prescribed 15 min (0.9 ml) and I realized my mistake a few hours later and, terrified, called on the old lady. She told me that she had taken one dose immediately on getting home and that the tinnitus had stopped. I asked her to take no more to see how long the effect would last. When I last saw her a year later the tinnitus had not returned.

Injection of Hydrocele

Prof CHARLES WELLS (Liverpool) writes: I refer to the answer under 'Any Questions?' (May 10 p 665). All the sclerosing solutions are very painful indeed, and a local anaesthetic should be injected into the sac (and subsequently run out again) before the irritant is put in. A second important point is the risk of injecting the fluid into the tissues outside the tunica. The cannula should be pushed well home when the sac is still full.

Treatment of Scorrhoea

Mr THOMAS WILSON FRCSE (London, NW6) writes: I treated a similar case to that published (May 17 p 705). (1) Wash the scalp in warm water, then dry and apply ung metallorum to the roots of the hair. (2) A *Staph aureus* vaccine. (3) A mixture containing mag sulph, acid sulph dil, spt chloroform, nuc vomicae inf gent co. (4) Ung metallorum to the axilla and the genital crural regions. My case is now quite well.

Surgical Rubber Gloves

Doctors in private, general or consulting practice requiring surgical rubber gloves for professional use are reminded that they should apply to the Secretary of the Central Medical War Committee British Medical Association House Tavistock Square London WC1 marking the envelope "Gloves" in the top left hand corner and enclosing a stamped addressed envelope for reply. They will then receive a booklet of six certificates.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Atlix*. *Western London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1 on receipt of proofs. Authors overseas should indicate on MSS if reprints are required as proofs are not sent abroad. ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1 (hours 9 a.m. to 5 p.m.) TELEPHONE: EUSTON 2111. TELEGRAMS: *Britmedads Western London*. MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association, TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecra Western London*. B.M.A. SCOTTISH OFFICE, 7 Drumsheugh Gardens, Edinburgh.

LONDON SATURDAY JUNE 21 1947

SOCIAL AND OCCUPATIONAL FACTORS IN THE AETIOLOGY OF SKIN CANCER

BY

JOHN A RYLE, MD AND W T RUSSELL, DSc

(From the Institute of Social Medicine Oxford)

The causes of human cancer, apart from the influence of specific carcinogenic agents and of chemical and physical factors the components of which may or may not be carcinogenic, are to be sought broadly in heredity, age, sex, and certain social and occupational influences. Berenblum (1944), although reintroducing the word "irritant" in a sense in which it is not usually employed, has discussed the two questions (1) Are all irritants potentially carcinogenic? and (2) Are all carcinogenic agents irritants? To the first he concluded that the answer is "No", to the second, that all direct carcinogens are irritants. He also concluded that non-carcinogenic irritants may facilitate the progress of a pre-neoplastic lesion to cancer.

There is strong evidence for genetic predisposition in the case of cancer originating in polyposis of the colon, and Jacobsen (1946) has lately added to existing information important material bearing upon a similar predisposition in the case of breast cancer. While it is not strictly correct to speak of cancer itself as heritable, the existence of a cancer diathesis may be held to be established, at any rate in respect of certain histological types and anatomical sites, in man. It has also been experimentally demonstrated for mammary cancer in mouse strains.

Age in man may be assumed to lend its contribution partly through longer exposure to effective stimuli and partly, perhaps, through a changing reactivity of tissues dependent upon hormonal or other chemical influence. Sex, through local injury or inflammation (as in the case of cancer of the cervix), or through hormonal influence (as in the case of ovarian, breast, and prostatic cancer), is clearly an important factor. More remotely, sex influences may also reflect social changes as these impinge upon the marriage rate, fertility, and parity.

The Registrar-Generals' standardized mortality comparisons (1930-2) suggest that lower socio-economic status predisposes in some way to cancers of the upper alimentary tract and the skin, both of which give a death rate in social class V approximately twice that obtaining in social class I, with a steady gradient in the intervening classes.

Skin cancers, although not numerous in the population by comparison for instance with those affecting the breast and alimentary tract, have this advantage—that they can be diagnosed with greater certainty and that there can be little doubt about the accuracy of certifications. The skin, considered as an external organ exposed to recognizable environmental stresses of a chemical or physical kind which vary appreciably both in duration and in degree with social circumstances and nature of employment, may thus prove

particularly worthy of investigation from the point of view of cancer aetiology.

It has long been accepted that soot, pitch, tar, and shale oil give rise to occupational cancers of the skin, that x-ray burns and prolonged thermal injury can lead to cancerous changes, that chronic ulcers and arsenical and other forms of dermatitis may end in malignant degeneration, and that the starting-points of skin cancers include warts and moles and other initially innocent tumours. But cancer of the skin can also arrive independently of these influences. If social factors can be shown to have importance on the basis of statistical correlations, and if skin cancer (in common with a number of other diseases) is found to discriminate against the less privileged classes, then the most likely local factors would seem to be exposure to atmospheric dirt—whether through grimy occupations or lack of bathing facilities, or both—and, in the case of some other occupations, exposure to the ultra-violet radiations of direct sunlight. This, according to Molesworth (1927), with his extensive Australian experience, may be an important factor in outdoor workers, and especially in those whose skins do not acquire the protection due to tanning. In Australia, as contrasted with England, lupus is very rare and epithelioma of exposed sites very common. If dirt is an important factor, the sites of cancer might be expected to include those in which it is most apt to lodge. The listed sites for skin cancer do, in fact, include the external ear, the canthus of the eye, the umbilicus, the anus, the scalp, and the neck. These sites, like the scrotum, are apt to be more infrequently and ineffectively washed than some other parts, and their anatomical structure encourages the deposition and retention of atmospheric soot or other dirt. It must be noted that the face as a whole has been recorded in some mortality tables (see below) as showing a much higher incidence of skin cancer than other sites: the ear has second place. These parts are exposed to grime and heat in some occupations, but the face is certainly more likely than the rest of the body surface to be subject to daily washing. On the other hand, it is more exposed to the ultra-violet rays of sunlight than any other part. In considering aetiological factors in skin cancer due regard must be paid to the type of cancer as well as to its site. It would be unreasonable to suggest that social or occupational factors play a major part in melanomata originating in pigmented moles or in Kaposi's idiopathic haemorrhagic sarcoma. They might, on the other hand, have a significant association with basal or squamous-celled epitheliomata. Unfortunately—lacking, as we do at present any

readily available morbidity figures—it is difficult to discover the incidence of the several types of skin cancer or their incidence in relation to site. The best that can be done, therefore, is to consider the mortality of skin cancers as a whole, and their sites where possible, and to see whether any suggestive correlations can be effected with such factors as sex, geography, social class, or occupation. We are here concerned with statistical material drawn from the *British Isles* only.

Scrotal Cancer

In a very interesting paper on the social distribution of cancer of the scrotum and penis, E. L. and N. M. Kennaway (1946) indicated that cancer of the scrotum, unlike cancer of the penis (quite apart from the occupational cases) a definite social class distribution, and that its mortality, and presumably its incidence, should be considerably reduced by the elimination of causal social factors. It would even seem proper to infer from the evidence presented that if all classes could enjoy the advantages experienced by social class I (Registrar-General's classification)—whether in respect of freedom from cutaneous irritants or of facilities for frequent bathing, or both—scrotal cancer would disappear. The suggestion was made in an earlier paper by E. L. Kennaway (1925) that atmospheric soot may be the operative factor and that all town dwellers are in some very slight degree liable to chimney-sweep's cancer. The scrotum and penis, as contiguous parts and both protected from sunlight, supply particularly convincing data. Possibly the rugose character of the scrotal integument facilitates the lodgment of grime in undue degree.

In view of the importance of these conclusions it was deemed of interest to examine the statistics of skin cancer generally, excluding the penile and scrotal forms, to measure the magnitude of the problem, the secular trend, the geographical incidence, and the possible relationship between cutaneous cancer and social and environmental factors.

The data utilized in this study were obtained from the Annual Reports of the Registrar-General for the United Kingdom and Eire, and particularly from the Decennial Supplement, 1931, containing occupational mortality tables for England and Wales. For the most recent statistics of the disease in England and Wales we would like to thank Dr. Percy Stocks, who supplied us with the unpublished data of the age incidence for the years 1942 and 1943.

Incidence of Skin Cancer

The mortality due to skin cancer is not numerically unimportant, since in 1943 it caused 1,094 deaths—626 were in males and 468 in females.

(a) *Secular Trend*—The secular trend of the age-specific death rates has recently been described by Stocks and Mackay (1946) for the period 1911–44, and they stated that the skin cancer mortality began to decline at ages over 55 about 1931. They also presented data in the form of a Comparative Mortality Index (1938 basis) for each year between 1933 and 1944 for males and females separately, and their results are reproduced in Table I. In stressing

TABLE I—Comparative Mortality Index (1938 Basis) Cancer of Skin (Scrotum excepted)

Year	Male	Female	Year	Male	Female
1933	1.032	1.078	1939	0.942	0.873
1934	1.021	0.965	1940	0.932	0.896
1935	0.960	0.986	1941	0.945	0.850
1936	1.024	0.989	1942	0.849	0.890
1937	0.997	0.992	1943	0.938	0.881
1938	1.000	1.000	1944	0.812	0.860

the merits of this new method of measurement Stocks and Mackay state: "This comparative mortality index shows at a glance how the real rate of mortality at all ages compares with that in the year 1938 taken as a basis. Furthermore, by simply dividing one index by another the proportionate increase or decrease in any one year compared with any other year can be arrived at." The figures in the table indicate that a satisfactory improvement has occurred in recent years, and it is reflected in the fact that the average CMI both for males and for females in the two years 1943–4 was 15% less than the corresponding values in 1933–4.

(b) *Geographical*—There is a distinct geographical picture in the mortality from skin cancer in the United Kingdom and Eire, and since each country classifies its statistics according to a uniform standard—namely, No. 53 of the Detailed International List of Causes of Death (Fifth Revision, 1938)—the variance in their statistical experience must be ascribed to the influence of some localized causal factor rather than to any divergence in classification. Here it may be of interest to specify what is officially included under the heading No. 53 of the International List. The following is the specification according to the manual published in 1940:

* Cancer of abdominal wall	Cancer of scalp
" anus	" umbilicus
" auricle of ear	Epithelioma of neck
" buttock	* Malignant dermatitis
" canthus	* Pitch cancer
" cheek (external)	Rodent ulcer (site stated)
" ear	* Rodent ulcer (site not stated)
" face	* Tar cancer
" nose	* X-ray cancer
" perineum	* Epithelioma (unqualified)
" pinna	

*Denotes that the cause of death is referred by the Registrar General for England and Wales to the certifying practitioner for further information.

To avoid comparisons based on direct standardized death rates, which for Northern Ireland, Eire, and Scotland would be subject to large sampling errors in view of the small number of deaths on which the age specific death rates in these countries are based, the analysis was made on the basis of indirect standardization. For this purpose the age mortality rates from skin cancer for males and females in England and Wales for the triennium 1941–3 were used as a "yardstick." These rates at ages were applied to the populations at the corresponding age groups in each of the three countries in question and the calculated or expected number of deaths for males and females were thus obtained. The number of deaths actually recorded in each country during the triennium was then compared with the calculated number, and the significance of the difference was measured by the formula:

$$\frac{\text{Actual} - \text{Calculated}}{\sqrt{\text{Calculated}}}$$

When the difference in any instance exceeded three times its sampling error the result was regarded as being statistically important. The results are given in Table II, in which the excess mortality from skin cancer in both parts of Ireland as compared with England and Wales is

TABLE II—Showing the Actual and "Calculated" Number of Deaths from Skin Cancer during the Period 1941–3

Country	Males			Females		
	Act	Cal	Act - Cal	Act	Cal	Act - Cal
			$\sqrt{\text{Cal}}$			$\sqrt{\text{Cal}}$
Scotland	150	208	-4.0	174	156	+1.4
Northern Ireland	98	56	+5.6	60	37	+3.8
Eire	230	156	-5.9	120	90	+3.2

For males and females the difference between the actual and calculated number of deaths is five times and three times, respectively, greater than its sampling error.

In Scotland the female experience was only slightly in excess, but for males the recorded deaths were much fewer than would be expected to occur according to the statistical experience of males in England and Wales.

Sites of Skin Cancer

In view of the high mortality from skin cancer in Ireland compared with that in England and Wales, and also of the fact that its statistical distribution according to site of occurrence is published in more detail in Northern Ireland than is the case for the other home countries, it was of interest to ascertain the frequency of site involvement in that region of the country. The results for the period 1941-3 are shown in Table III.

TABLE III—Incidence of Skin Cancer According to Site in Northern Ireland

Site	Males		Females	
	No.	%	No.	%
Head	7	7.1	5	8.3
Face	20	20.4	—	—
Neck	53	54.1	46	76.7
Trunk	—	—	1	1.7
Arm	4	4.1	2	3.3
Leg	—	—	1	1.7
Hand (skin of)	4	4.1	—	—
Hand (inner wall)	1	1.0	—	—
Foot	1	1.0	—	—
Other skin	8	8.2	5	8.3
Total	98	100.0	60	100.0

It will be noted that for both sexes the face is the principal location. Face, cheek, and ear in males account for 16% of the skin cancer deaths. For females, face and neck contribute 85%. No female deaths from cancer of the ear are recorded. Dr Berenblum suggested to us that protection of the female ear from sunlight by hair might have to be considered in explanation of this sex difference. Without more detailed information bearing on occupations, these figures cannot be fully explained. Since a high proportion of the population in Ireland are agricultural workers and the women are included among these, suspicion might seem to fall on sunlight rather than atmospheric dust, but here it should be noted that Ireland has a humid atmosphere very different from that, for instance, of Australia. No similar figures relating to the site of lesions in urban England are available for comparison.

Social Status

In the very interesting statistics which the Registrar-General has published in the Occupational Mortality Tables for England and Wales covering the period 1930-2 he has concentrated chiefly on the age period 20-65 years, and the standardized mortality ratios which he has published relate to this period of working life. There are sound reasons which justified or determined this restriction. But in a discussion of occupational incidence on disease, particularly in relation to cancer, it is obviously important to include, if possible, the statistical experience after age 65, because many of the deaths occur at this stage of life and it may be that an occupational factor in the causation of cancer, at least in some sites, may not fully declare itself until the man has retired from work. But a difficulty arises and it has been pointed out by the Registrar-General in the following terms: "Statement on the Census Schedule of the former occupation of married males tends to be omitted as life advances." The statement in death registration the statement of the last

occupation can nearly always be obtained, and the result is that at ages after 60 the population returned as never occupied is too large, and the populations of the occupied are too small, to correspond with deaths similarly classified."

From an examination of the available data for the period 1930-2 the Registrar-General was satisfied that the error introduced in this way was of much less importance than at the previous census. "At ages 65-70 the transfer of the population, if spread evenly over the occupied classes, would increase the numbers at risk by only 3% throughout, and reduce the mortality rate in the same proportion." At ages 70-75 the reduction in mortality would amount to approximately 6% and at age 75 plus to about 11%.

To test the possible effect of this transference on the mortality from cutaneous cancer the standardized mortality ratio at age 65 plus was calculated for certain combinations of the Registrar-General's five social classes I and II representing professional and executive classes, III, skilled workers, IV and V, unskilled workers and labourers. (The standardized mortality ratio (S.M.R.), usually expressed on a percentage basis, indicates whether the recorded deaths in an occupation are equal to, greater than, or less than the "expected" number.)

The trend of the ratios according to their social significance was then compared with that shown by the similar ratios for the age period 26-65, which may be regarded in the present instance as the "control series." If there be a parallelism in the trend in the ratios at the two contrasted age periods, then it would be fairly legitimate to assume that the apparently disturbing phenomenon to which the Registrar-General called attention is not of very serious import so far as cutaneous cancer is concerned. The results are stated in Table IV, where it will be observed that the

TABLE IV—Actual and Calculated Deaths and S.M.R. from Skin Cancer during 1930-2 in England and Wales

Social Class	Age Group								
	20-65 Years			65+ Years			20+ Years		
	Act	Exp	S.M.R.	Act	Exp	S.M.R.	Act	Exp	S.M.R.
Males									
I and II	87	120	73	286	303	94	373	424	88
III	242	257	95	472	534	88	714	791	90
IV and V	244	199	123	579	404	143	823	603	136
Married women									
I and II	49	54	91	34	49	69	83	103	81
III	107	114	94	90	86	105	197	200	99
IV and V	92	79	116	76	59	129	168	138	122

correlation between mortality and social status shown for males and females in the age group 20-65 is also evident in the age group 65 years and upwards, but more so for females than for males. In view of this fair degree of similarity of gradient of the mortality of each of the two age groups it seemed legitimate to aggregate the statistical experience and base the discussion on the combined age group 20 years and upwards, as has been done in Table IV.

For wives, the S.M.R. in the combined classes I and II is 81, and it increases uniformly, attaining a value of 122 for those lowest in the economic scale. This marked association in the case of wives would seemingly rule out the possible influence of a purely occupational causation. On the other hand, the less uniform gradient in the mortality of males according to social grade would suggest that both occupational and environmental factors may be involved. In an attempt to disentangle any such causal connexion, the standardized mortality ratios for particular occupations were placed into four groups.

Group A represents workers with advantages in the matter of opportunity for cleanliness and working largely indoors. This

group in which there were 13 occupations comprises the professional classes clerical grades typists and policemen. Their social and economic equivalents in terms of the Registrar-General's classification are represented by social classes I, II and III.

Group B is composed mainly of occupations nine in number which are ascribed to social classes III, IV and V. They are coal hewers and getters, coal other workers below ground, coal other workers above ground, iron ore mine workers below ground, stone miners and quarriers, potters, ware makers, etc., textile strippers and grinders, cotton bricklayers, masons, etc. The work involved is heavy and dirty, especially in the coal fields, but the workers in coal who numerically dominate the group probably utilize to an increasing extent the facilities for cleanliness afforded by pithead baths. Long exposure to sun light is not a particular hazard in these occupations.

Group C—In this group there are five occupations: agricultural and gardeners, labourers (social class IV), builders, labourers (social class V), other workers (navvies) in buildings, etc. (social class V), water transport and dock labourers (social class V), general labourers and unskilled workers (social class V). The men engaged in them perform arduous labour involving grime and dirt. The workers tend to conform to types either indifferent to or having inadequate opportunity for desirable standards of cleanliness. They also include categories working in the open air.

Group D is composed of only two occupations: furnacemen and rollers and skilled assistants (social class III), boiler firemen and stokers (social class IV). This group relates to men higher on the average in the social and economic scale than either group B or C, but the men experience in their occupation the effects of prolonged exposure to both grime and excessive heat.

The statistical experience of each of these four categories of workers aged 20 years and upwards from skin cancer during the triennium 1930-2 is shown in Table V. It will

TABLE V—Actual and Calculated Numbers of Deaths and S.M.R. from Skin Cancer in Four Different Groups of Male Workers aged 20 years and upwards during 1930-2 in England and Wales

Group	No of Occupations	Deaths		S.M.R.
		Actual	Calculated	
A	13	103	148	70
B	9	130	127	102
C	5	511	319	160
D	2	27	12	225

be seen from the figures that there would appear to be both a social and an occupational factor involved in the causation of skin cancer, and that the latter is seemingly the more important. In group A, representing as it does workers who have a high standard of cleanliness, the mortality is 30% below the average, but in groups C and D it is 60% and 125% respectively in excess.

An attempt was made to evaluate the incidence of skin cancer amongst married women in groups A, B, C, and D. The experiment was not entirely successful because some of the occupations which provide the male groups were not listed for women in the Mortality Supplement, since only a few deaths from all causes occurred in them during the period 1930-2. The number of occupations for which the facts were ascertainable was 7 in group A, 6 in B, 4 in C, and 2 in D. This reduction detracts somewhat from the reliability of the calculated mortality ratios, which for age 20 and upwards were found to be

Group	Actual Deaths	Expected Deaths	S.M.R.
A	12	16	75
B	29	25	116
C	96	63	152
D	1	3	—

The operation of a causal social factor is evident in the gradient of the S.M.R.s from group A to group C—a gradient similar in character to that shown for males. The data in group D are insufficient for comment.

Unfortunately we have no means of ascertaining the specific sites involved in the excess indicated in groups C and D for males, as the Registrar-General does not publish the statistics for individual sites. The reason is, of course, the paucity of existing data. It would nevertheless be instructive if the statistics were available, particularly in their relation to occupation. The social circumstance and occupation of sufferers from skin cancer affecting sites which tend to retain dirt (ear, canthus of the eye, umbilicus, anus, scalp, and neck), and of cancers in other parts (face and hand) exposed to light, would make an interesting special inquiry for hospital departments of dermatology employing a standard method of recording. In view of the comparative rarity of cases, such an inquiry would need to be collectively, perhaps internationally, organized. We know from the information published for the other home countries that the face is the principal site involved. In Northern Ireland it constituted 54% of the total deaths from skin cancer for males (82% if cheek and ear are included) during the period 1941-3. The ear had second place with 20%. Somerford (1930), from a study of cases of cutaneous cancer, 57 of which were squamous-celled and 175 basal-celled, found that the face was the most common situation for both forms. From this he drew the following conclusion: "This fact in our opinion is against an occupational cause, since the face is the part of the body least likely to be brought into contact with irritating substances used in any occupation." This conclusion (for the face is the only part never covered) is not justified. In several of the occupations named (groups B, C, and D), grime or heat, or grime plus heat, are surely agents which cannot be overlooked. In others, outdoor work with long exposure to sunlight must be taken into account. According to group D of the present series, an occupational factor does seemingly operate, but at present it cannot be said if the facial site is the main involvement. More detailed statistics of location are required before any dogmatic assertions can be justified.

It would be an interesting paradox if soot and sunshine should both prove to have aetiological importance in skin cancer. In practice, however, it would be reasonable and not inconsistent to purify the atmosphere, to provide the people with baths, and to suggest protective measures for those unduly exposed to the radiations of the sun.

Summary and Conclusions

The annual number of deaths from cancer of the skin, excluding that of the penis and scrotum, is approximately 1,000 per annum in England and Wales, and the mortality in males is about 70% in excess of that in females.

The mortality for both males and females from cutaneous cancer is much greater in Ireland than in England and Wales, whereas the Scottish male experience is decidedly more favourable.

The face is the principal site involved. The ear is next in frequency.

The mortality has a definite gradient with social grouping for the wives of workers, but for the males it would seem to have both a social and an occupational relationship, and the latter is seemingly the more important.

These findings, and the anatomical character of some of the sites affected, suggest, on the one hand, that atmospheric soot or other grime (as in the case of scrotal cancer) may need to be considered as an aetiological factor. On the other hand, ultra-violet radiation from the sun may be responsible for skin cancers in exposed sites. Heat or heat plus grime, may be

operative in such occupations as that of furnacemen, if face and hands should be shown to be frequently involved in these workers.

Classification according to site in official returns is needed to increase the value of correlations with occupational or other factors. Correlations with geography, or hours of sunlight in different parts of the British Isles and elsewhere should have value.

We are grateful to Prof. E. L. Kennaway for criticisms and small corrections embodied in the text.

THE MEASUREMENT OF HUMAN SKILL*

BY

F. C. BARTLETT, C.B.E., F.R.S.

The Grouping and Stability of the Constituent Items in Skill Performance

I now turn to the second of our three main problems—that of the grouping and stability of the constituent items in a skilled performance. This has been more often studied outside than inside the laboratory. The reason is that fully controlled investigations have been far too occupied with skill of the derviled repetitive kind, the order of constituent items being is definitely prearranged as their character. In daily life this happens very rarely. Variety of order or sequence is combined with a high degree of uniformity of issue or aim.

In *Live Hand*† a former Cambridge University golf captain has written what Bernard Darwin calls "an impassioned plea" for hands as the key to the game. He watched an Open Championship in America, and thus he describes the play of the experts: "Through the feel of their hands they swung the club head and brought it to the ball with the maximum speed and accuracy at the moment of impact. It seemed as if they had stayed behind the ball until after it was hit and that the whole weight of the body flowed in behind the shot." And so also for every other game of skill. The expert may discover his own key, the one thing or the few things that must be used with conscious effort and then everything else will happen right. The bother is that the expert is apt to treat his key as the master whereas differences of bodily build, and consequently the mechanics of bodily action, should make it clear that in this case as in many others, one man's salvation is another man's downfall.

We will begin with some simple but most illuminating experiments which have, however, received little attention. They are concerned with the sense or direction of movement in the manipulation of controls. Any direction or sense of control movement can easily be made to produce a corresponding movement of display: an upward adjustment of a lever for example may produce an upward, downward, right or left movement of a pointer or a spot of light. Under these circumstances practically everybody will tend to make fewer mistakes with the up-up-down-down than with the more and more culminating with the up-

down relation. Speaking generally, whenever, as in every form of skill, sensory reactions of differing mode have to be combined some combinations are fundamentally easier and more efficient than others. The study of these preferred combinations opens up an immense field of experiment which has so far been little explored.

It is possible to alter the sense of the manipulatory movement during the course of the experiment without the knowledge of the operator. Nearly everybody now makes a greater amount of error. But the increase is significantly greater in some cases than in others. Some operators make the display the "key," and are delicately perceptive of any change in visually presented motion. These are readily adaptable, changing an upward into a downward bodily action very often without at all definitely knowing what they have done. Others make their "key" the feel of the movement itself, and for these the required adaptation is relatively difficult. It seems as if, paradoxically, the muscular part of the skilled operation is the more efficient the less is known about it. There may be, and I think there are, instances in which the exact opposite is the case, but it is not very easy to find them.

Even when this does happen, as perhaps sometimes in the "feel of the hands" in golf, it never is the whole of the movements that emerge into consciousness. In this instance the enormously complicated follow-through of the whole body, with its complete readjustment of posture, "flows in" automatically. And when we think about it this becomes less paradoxical than it seems at first. For absolutely every skill has its immensely complex embryological basis, the first 40 weeks of which in the vast majority of human performers has proceeded with strikingly little direction from the interoceptive senses. During this early period all the major fundamental phenomena of posture are achieved. It is customary to regard them as coming to centre about and grow out of the three main types of postural reflex—the attitudinal, the righting, and the statokinetic. But these have none of the fixity and individualization which the later reflexes, dominated by external stimuli and the play of the special senses, show. They appear, disappear, and reappear. Though their pattern remains reasonably constant the ancillary movements which stream out from them change in order, direction, and number as they start now from one position and now from another.

Yet the structure which is later going to dominate all this machinery of the motor and muscular systems, as everybody knows, appears remarkably early and long before it can have much effective use. When the time comes for senses like the eyes and ears and for the central nervous system to play the leading parts in development—for learning proper to take the place of maturation—they have an immense and complex substratum of movement to play with.

So it is not as surprising as might be supposed that one of the very common features of diminishing skill is an increased awareness of what the whole body is doing. We found that the air pilot, fresh and keen, follows his instruments and their signals closely and lets all his bodily equipment, so to speak, do as it likes. When impulses from the body do "rise into consciousness," as the common phrase puts it, they are interpreted in terms of the machine, as in steep turns and banks, in rapid acceleration, in climb and dive. But as he gets tired and his skill tends to break up, the messages from the body become, in their own right, insistent and oppressive. He is cramped, too hot, or too cold, there is pressure here and there, sometimes it seems that the instruments cannot possibly be right.

The really important upshot of all this is that every skill has its key features. They differ from case to case and

* The second of two O. J. Sharp Lectures given at the Royal College of Physicians of London on Jan. 23. The first lecture was on "The Psychology of the Human Factor in Aviation".
 † *Live Hand*—London: Adam and Charles Black, 1946.

from body to body, but they are always there. In by far the great majority of what may be called "educated skills" they consist in operations of the distance senses and of central selection and judgment. If we can find them and discover how they are related to their unconsidered setting or scheme of posture and ancillary movement, the problem of how to measure skill has become simpler. It is the key features whose course must be plotted, whose efficiency must be recorded. In these last few years this has been done, or partly done, for many tasks: for the pilot in the air, for the tracking of targets, for the radar operator, for a number of skills which alternate periods of monotony with periods of intense activity, for the high speed reading of dials and banks of dials, for the sending and reception of messages in code, for steady winding with varying load. In all these—and the same is true for innumerable other activities for which similar methods can now be developed—it is not every descriptive item in a repertoire of skill that must be recorded and assessed, but the leading functions only.

When, with this in mind, we stand back and look at skill as it is done, we can perhaps see clearly how it is that the skilled performer must know more *what* to do than *how* to do it, and that at once leads us to our third problem, the functions of "the task."

Relation of Achievement to Means of Achievement

The best approach is to consider an actual problem. I will choose one which, in this field, is fairly simple—the operation of the bomb-aimer. For practical reasons this operation has been submitted to a very thorough experimental study. The area bomber approaching his target can see that its limits are marked by a number of flares of given colour which act as target indicators. His task is to judge as accurately as he can their central point of impact and to drop his bombs as near this as possible. Obviously the limits of area cannot for certain be exactly indicated, and the flare pattern can never for certain be exactly repeated. The number and clustering of the target indicators are liable to rapid and wide fluctuation. Sometimes a pattern will be relatively symmetrical, and sometimes there will be outlier flares which are known to constitute a kind of key item in the display and to distract judgment. Now it is possible to reproduce this situation in miniature, so that the flare patterns appear at the rate and with the visual properties which they have under operational conditions, and the bomb-release control movements are the same. Naturally much of the excitement of the operational task is lacking, but a few experiments showed that this makes little difference. The errors produced in the experimental setting were almost the same, in direction and amount, as those made in operational conditions.

In the experiment the bomb-aimer is briefed so that he knows the general character of the area which is to be delimited. He watches the target indicator pattern approach, and presses the bomb-release switch at what he judges to be the correct moment. Two points are all important: first, he must precisely understand what he has to do—that is, to drop his bomb as near as possible to the central point of impact of the flare pattern—and, secondly, having performed his job, he must know the exact degree of his success. The common belief that "practice makes perfect" is not true. It is practice *the results of which are known* that makes perfect. There is some evidence, though it is not quite conclusive, that the more the results can be expressed positively in terms of success the better.

Under these conditions a normal operator will improve very rapidly and maintain his improvement from trial to trial. Now suppose we take a set of entirely new target indi-

cator patterns, so that, given a constant fixation point, the retinal areas stimulated are different ones, and suppose we demand a new type of bomb release pressure, so that the tactile areas and the muscles used are different. Provided these two things remain constant—the task and the knowledge of how successfully it has been performed—and there is no very marked change in the general environment, the skill which has been acquired remains with no increased time requirement and no greater fluctuation of success within a wide range. Ask the operator how he has done his work, and different persons may invent, or at any rate describe, very differing techniques. The plain fact is that most of them do not know and do not need to know, for the precise sensations and movements develop out of the setting of the task much as the specific arm or leg movements grow out of the attitudinal reflex, and they are fixed by knowledge of success as the very early movements must be fixed by some kind of biological efficacy, and with a similar but even wider range of variability.

Now, I think we have assembled all the chief items required for the experimental measurement of those forms of skill which combine bodily and mental behaviour. First it is necessary to have some direct measure of achievement. This may, however, throw no light on the means of achievement. Since we must know not only how well a thing is done but within what limits of success it can continue to be done, a measure of immediate achievement is not enough. Continuance of skill depends chiefly upon the maintenance of key features, both in receptor and in effector response, and on their time relations. These key features may vary from person to person or from group to group, but in many cases they remain remarkably constant for all, and always they display great constancy from effort to effort in the same operators or operator groups.

Receptor key items can usually be determined experimentally by the design of the display or stimulus pattern. The important factors are positional, directional, intensive, qualitative—as in the cases of colour, form, clustering, or pattern qualities—and numerical. It must be admitted that at present the determination of effector key items demands much the same process as clinical diagnosis, and perhaps it always will, for, as we have seen, the exact movements made in skilled performance are apt to escape any known form of exact objective registration. When key features are determined the kind of measure that is needed is a plot of their course, of the way in which and the degree to which they appear and reappear in continued exercise.

Finally, since all skill can be rightly treated as a continued interlinkage of receptor and effector responses, and the efficiency of this depends most of all upon timing, the third measure that is required is one of what I have called "total reaction time" in a series. The measurement of achievement tells us nothing for certain about means, the plot of key items by itself gives us no information about the efficiency with which the task is done, the record of timing by itself does not indicate what are the key features or what success attends the effort. All three are needed.

Is it possible to simplify still more, to find a single measure which will indicate what may be called the "level" of skill in a given individual? The answer is "Yes," but the simplification may be more apparent than real.

The best single measure of skill level is one of its "range of constancy," its degree of resistance to disintegrating conditions. This measure can be expressed in any one of the three basic ways. But a record of degree of achievement alone can obviously be extremely misleading for with interference conditions a less successful achievement must be equated with a better one. Apart from a very prolonged experiment it is not possible to know how to do

and at the best it can be done only in a very approximate and statistical manner. A plot showing how key features are maintained is better, but is rarely satisfactory because use it is not uncommon to find the operator switching from one set of key features to another, holding one for a while and then switching back again. And, the continued exercise may itself be a disintegrating condition. This may well be one of the best ways of maintaining level of skill. A random fluctuation of key features is, however, always a sign of the imminent break-up of skill. If level of skill is defined by its capacity to resist interference, the measure of total timing of successive responses is the best single criterion, for if timing gets out of step nothing can for long stop the complete break-up of the skill. A combination of all three types of measure, however, remains the best criterion that can be used.

Is the Exercise of Skill a Discontinuous Function?

I do not now turn to a brief and, I am afraid, very incomplete consideration of a fundamental question about the nature of operative skill which is raised by all these investigations. At the very beginning I suggested that skill comes with the graded response, when the characters, and especially the intensive characters, of the stimulus are faithfully reflected in the response. But how are we to picture the grading? It has long been evident that from an efficient sensory point of view there is no such thing as an absolutely continuous grading of response, but rather a series of steps which, set end to end, so to speak, produce an appearance of continuity. Moreover, these steps are affected by a large number of conditions, among which very important ones are, in some cases, the rate of application of the stimulus, the duration of the stimulus, and the rate of adaptation of the peripheral organs. Within limits the faster the rate of application, the more durable and the more within the range of adaptation the stimulus, the smaller the steps.

Similarly the effector side of the process may have a discontinuous character. In positional tracking, for example, an operator may appear to move continuously from his starting point on to the target, and then, when it is stationary, or moving at a regular rate in the same direction, hold it continuously. But experimental records show that the normal thing for the operator to do is to produce a series of oscillations each lasting very consistently for about one-quarter to two-fifths of a second. With other forms of control the oscillations have a somewhat longer duration but are even more marked.

Other illustrations are better known. For example, in scanning a visual field for the identification of an inconspicuous object the observer will consider that he is making a smooth continuous exploration. But it is very easy to demonstrate that he proceeds in a series of saccadic eye movements with interfixations. The pattern of movements and pauses varies considerably from individual to individual, but remains very consistent for any particular person. The mean fixation time, in free search for short objects is approximately half a second with a mean interfixation interval of 5°.

These facts and many others appear to suggest strongly that human skill is basically a discontinuous function both on the receptor and on the effector sides. But about the important questions which arise if this is the case we know little. How the discontinuity of reception is related to that of action is obscure, but each must affect the other in continued exercise. Moreover, it has been practised a few times the picture is

complicated by anticipation and some factor very like inertia which may well tend to counteract any initial discontinuity.

Meanwhile it does seem as if we have to consider the human being as fundamentally operating somewhat after the manner of the ballistic galvanometer. For each skill there may be some minimal effector impulse which, once it comes into operation, prevents any further exteroceptive change from doing anything at all until the effect of the impulse and recovery from the effect are complete. If so this may be why timing and variations of timing are the central significant measures for all kinds of bodily skill. It would also follow that if ever a mathematician adequately descriptive of human skill becomes possible, it will be a mathematician of discontinuous functions.

Mental Skill

Last of all I must say something about those highly developed forms of skill which are called mental. The most impressive characteristic of mental skill is its use of symbols, and particularly of symbols which can be given a permanent form. The distance senses upon which psycho-physical skill mainly depend set man free from the confines of immediate space. The symbols and their means of preservation which he has developed make possible enormous strides further in the same direction. They mean that timing, the vital feature up to this point, becomes of little direct importance or takes new forms. Now for the first time a new type of correction becomes possible, before the skill product need be given any public expression, actual or possible. In verbal skill it may be a substitution of word or phrase, in plastic skill of form, colour, mass, in music of tone, melody, with the items substituted picked out here and there and not in any settled serial order.

We are forced to use new vaguer criteria, of rhythm and proportion (which are no doubt still forms of timing), of meaning, relevance, truth, beauty, fitness. These appear to be almost infinitely fluctuating. Are they perhaps only approximations—so far to be placed in no known scale of quantities—to human conventions widely but impermanently established, or are they measurable by the nearness of their approach to something fixed and final? We can only speculate.

There is one suggestion which I believe could be studied with reasonable control. It occurs in the deeply interesting book by Jacques Hadamard called *The Psychology of Invention in the Mathematical Field**. In this book he refers several times to the appearance of error in mathematical reasoning. "Good mathematicians when they make errors, which is not infrequently, soon perceive and correct them. As for me (and mine is the case of many mathematicians), I make many more of them than my students do, only I always correct them so that no trace of them remains in the final result."

"Time will have its revenges." Here perhaps it comes back on us in a new form. Maybe the best single measure of mental skill lies in the speed with which errors are detected and thrown out, a function which becomes possible only when skill has first a symbolic expression.

How is this done? We do not yet know, but we can set to work to find out, and if we do one thing is certain: we shall find that when man achieves the symbol and its permanent expression he does not really cut himself adrift from the age-long ways of the simpler kinds of skill. The topic replaces the task. Given the topic the words or numbers, or colours or tones, develop out of it as movements from the task. Both have their tremendous

* Princeton University Press, 1945 (in England, Oxford University Press).

embryology, so that in both cases there is no necessary prior recall of items before use. Generally what we style recall is use.

There is a very simple and rather beautiful experiment which Henry Head used that may, I think, give us a clue. Before certain of his aphasic patients he set a number of solid shapes of triangles, squares, cubes, and the like, which were to be viewed but not touched. The objects were covered and then either exactly similar or different ones were placed in the hands of the patient behind the patient's back, and he had to indicate whether the object now being tactually explored had or had not previously been among those seen. No patients had any difficulty in making the required identifications accurately, but the order of original exposure could not be indicated without difficulty and error. The identification of form was immediate and required no necessary prior recall of the visual qualities concerned. One sensory pattern—tactual—fitted another sensory pattern—visual—of different mode. Head called this process "matching". It could cope with shape, but order requires the use of a symbol of the word-type, and was out of the range of his particular observers.

Now it has frequently seemed to me that matching, the immediate fitting of one set of responses to another or of one content to another, may well be a process which has a much wider range than is often realized. For every task, for every topic, at every level of psychological development there are perhaps the fit reactions and expressions, and there is perhaps some mechanism characteristic of each level of development which can identify the ones that are fitting or throw out the ones that are unfitting.

I think, perhaps, that what Hadamard suggests in the case of the good mathematician is just as true of the great clinical physician. It is not that he makes fewer mistakes than less-skilled people, but that he knows his mistakes more quickly and does not follow them so often to the stage at which they become irremediable. After, sometimes long after, it may become possible to identify and quite definitely to characterize the item of error. But at the time there is literally nothing except the knowledge that to go on along this line will not fit. The several patterns and functions involved must be very different from those of direct sensorial matching, and the content used may require a highly abstract and symbolic representation, but fundamentally the process is the same at the high level as at the lower.

And, of course, if this is a right way of approach, mental skill, even in its highest reach, is not merely an approximation to temporary convention, but is an achievement of combinations of response which do, as a matter of fact, fit well together. Whether or not a measure of such skill can be obtained in terms of relative sensitivity to errors or false starts is indeed still a matter for investigation, but at least this hypothesis is not beyond the bounds of an empirical study.

NOTE—Most of the work which I have referred to in these lectures is as yet unpublished, though it has been the subject of a large number of reports. The great majority of them from the Cambridge Psychological Laboratory. I wish to acknowledge first the generous support by the Medical Research Council through their establishment of a Unit of Applied Psychology at Cambridge, by the R.A.F., chiefly through the Flying Personnel Research Committee, and by the Ministry of Supply, mainly through bodies concerned with tracking problems and the development of servo mechanisms. There is practically no member of the research and teaching staff of the Cambridge Psychological Laboratory who has not contributed in important measure to the success of the undertakings involved, but it is perhaps permissible to refer especially to the insight and initiative of the late Dr K. J. W. Craik and to the vital experimental studies of Dr W. E. Hick, Miss M. A. Vince, Dr D. Russell Davis, Dr N. H. Mackworth, Dr A. W. Carpenter, and Mr G. C. Grundley.

MODERN TREATMENT IN PSYCHOLOGICAL MEDICINE*

By

LOUIS MINSKI, MD., FRCP

*Medical Superintendent Sutton Emergency Hospital
Hon Assistant Psychiatrist St George's Hospital*

Progress in psychiatry was for many years slow, and hospitals for mental disorders were used primarily for custodial care rather than therapeutic centres for such illnesses. Between the two world wars, however, considerable progress was made in the treatment of psychiatric conditions, and a milestone was passed when the treatment of GPI was successfully instituted by Wagner-Jauregg in Vienna in 1917. During the same period the treatment of agitated and restless patients was tried under continuous sleep by Klati of Switzerland and other workers, and this was found to be of considerable value.

It was recognized that schizophrenics rarely suffered from epileptic seizures, so trial was made of the treatment of schizophrenia by inducing epileptic fits with convulsant drugs, among them leptazol and triazol. It was found, however, that in those cases of schizophrenia in which depression was marked the improvement in the depressive element of the illness was striking, while the schizophrenia as a whole was not greatly improved. Depressive illnesses were therefore treated by artificially induced fits, with much more satisfactory results than in schizophrenia. This method of inducing fits by these drugs was, however, found to be unreliable in that fits did not always occur and often caused great fear and apprehension in the patients. The use of convulsant drugs was replaced by a machine which produced fits by passing an electric current through the head. The patient felt no ill effects, and the fits occurred in over 90% of cases.

Following the abandonment of the convulsion treatment of schizophrenia another milestone was passed by the introduction of the insulin treatment of schizophrenia, which was begun by Sakel of Vienna about ten years ago. Previously a certain number of schizophrenic patients recovered spontaneously by having remissions in their illness, but the prognosis and duration of the condition have been materially altered by the introduction of this form of treatment. At the same time that these physical methods were being developed, psychological methods were also being improved upon. Thanks to the work of Freud and various of his followers, such as Jung and Adler, the psychopathology of mental diseases was understood for the first time. Previously the patient's delusions, thought content, and actions had no meaning to the psychiatrist. Following on the work of Freud, however, it was possible to understand why the patient said, for instance, he was "too wicked to live" or why he was continually washing his hands, etc. From this understanding of the psychopathology of mental illness it became possible to probe into the patient's unconscious mind and so deal with the conflict which was the cause of his neurosis or psychosis. The technique of psycho-analysis was developed by those who themselves had been psycho-analysed, but this is a costly and lengthy form of treatment. Other methods of psychotherapy—to be discussed later—have been evolved for dealing with the patient's illness in a much shorter space of time, and in many cases are just as efficient.

At the outbreak of war in 1939 this roughly was the position regarding the treatment of psychiatric illnesses. It

* A paper read to the Sutton and District Medical Society on Feb 7, 1947.

The numbers of psychiatric casualties would be more the civilian members of the population as a whole while the Armed Forces would have their own psychiatric casualties also. Long and costly methods of treatment would not be possible for large numbers of psychiatric casualties as neither the psychiatrists nor the beds would be available. Various techniques of treatment were devised, and it is proposed to discuss those which are likely to prove of value in the treatment of psychiatric illness in civilian life, although they were first applied to psychiatric illness occurring during the war. For simplification, treatment may be divided into physical and psychological methods, but in most cases a combination of these can and must be used.

Physical Methods

Continuous Narcosis

For those suffering from acute anxiety, agitation, or manic reactions continuous narcosis is an invaluable method of treatment. By this means the patient can be kept in a state of twilight sleep for a period varying from 4 to 7 days. During this time he is completely cut off from his environment, and as a result his mind is in a state of complete rest. Various drugs, such as "somniafene," "aphorbitione," and "dial," can be used for this purpose, but in my experience sodium amytal is the most efficacious. This drug acts rapidly, is rapidly excreted, does not tend to accumulate in the body, and toxic symptoms are uncommon. The usual dose is 6 gr (0.4 g) every four hours while if additional sedation is necessary 2 dr (8 g) paraldehyde can also be given. The patient, who is kept in a darkened room, can be roused to take his meals and the next dose of sedative should be given after a meal and after he has used the bed-pan, etc., so that he is not disturbed unnecessarily. It is essential to see that plenty of fluids are taken, as this helps to ward off toxic symptoms. The usual check is kept on pulse, temperature, and blood pressure while the daily output of urine should be measured. When the patient is finishing treatment the dose should be gradually withdrawn, as instant withdrawal sometimes produces major epileptic seizures. On waking round from the drug the patient is often "muzzy" for a few days, but the result of the rest in many cases is to remove the acute anxiety symptoms when the patient is able to be approached from the psychological point of

where patients are undergoing continuous narcosis and their appetites are poor, modified insulin treatment can be combined with the narcosis with great effect.

Insulin Coma

This treatment is used for all forms of schizophrenia, but is said to be most effective in the paranoid types. It has been found of value not only in cutting short the attack but also in resocializing a patient for whom a poor prognosis would previously have been given. There are certain physical contraindications to this method of treatment, and in those patients who have had tuberculosis there is a definite risk of reactivating the infection, so for this reason it is unwise to use the treatment in such cases, nor should it be used where there are grave circulatory or kidney disturbances. The treatment can obviously be given only in hospital, with nursing and medical staff specially trained in the method. The ideal arrangement is to have a complete unit with medical and nursing staff in continual attendance during treatment, with emergency trays containing equipment for both nasal and intravenous methods of interruption of the coma always at hand. In addition, trays containing stimulants such as adrenaline, nikethamide, etc., should always be ready. As in the modified insulin method of treatment, the patient is given his injection of insulin at 7 a.m. fasting, the usual commencing dose being 10 units. The dose is increased daily by 10 units, and in a number of cases 300 units or more may be required to induce coma. The patient gradually goes into coma with profuse sweating, often stertorous breathing and restlessness, and is allowed to remain in coma for about half an hour. However, should he develop epileptic fits, irregular pulse, falling blood pressure, respiratory stridor, etc., the coma must be interrupted at once. As a routine this is done nasally by giving 33% glucose, if the condition is urgent it is given intravenously.

When the patient is roused he is rubbed down, put into dry clothes and a dry bed, and given sweetened tea and a meal. It is necessary to keep the pulse, respiration, temperature, and other such records carefully from the time he is given the insulin until he comes out of his coma, and such patients, after treatment, should not be allowed far from their ward, as they may develop late hypoglycaemia. Patients should be encouraged to carry some lump sugar or chocolate in case they feel faint. The patient is allowed up by lunch-time and then takes part in the other forms of treatment, etc. to be mentioned later. As with modified insulin treatment is given five days a week. Most favourable cases respond in two months, but if no improvement occurs after the third month the likelihood of recovery is poor.

Insulin Treatment

Many patients suffering from chronic neurosis, such as anxiety states, tend to lose weight and as a result feel that there is something wrong with their bodily health. In such cases their appetite is poor, they do not wish to eat, and a vicious circle is set up. Early in the recent war small doses of insulin were given to such patients in the morning, but it was found that by gradually increasing the dose the patient passed into a state of sopor and became comatose. The dose of insulin which starts at 10 units is increased to about 80 units is given at 7 a.m. The patient is allowed to remain in this state of sopor until he is given a cup of sweetened tea, and a small portion of food (as a substitute for sugar, etc.) is given together with his ordinary breakfast. He is allowed to go into coma, and after this treatment is given for five days a week for a few weeks the patient improves considerably and there is a large gain in weight. The positive effect of putting on so much weight is the main object of the modified insulin treatment, as it is of great value in the more chronic cases. The use of insulin is a feature in some cases

Electric Convulsion Therapy

This form of treatment is now used effectively in depressive illnesses. It has been found of most value in depressive illnesses which are constitutional or endogenous and arise from the personality of the patient. Where, however, the illness is reactive to an external situation convulsion therapy can be of help in giving a "fillip" to the patient when he seems to be stuck in a groove and unable to make progress. In those forms of depression occurring at the involutional period it is probably of the greatest value. Here again the contraindications are similar to those for insulin treatment, while patients with high blood pressure, arteriosclerosis, and brittle bones are not good subjects. The patient is given the treatment fasting and at our hospital he is controlled in a special jacket which helps in preventing fractures (the commonest being a

crush fracture of the lumbo-sacral spine) that occasionally occur, while a gag is inserted in the mouth to prevent tongue-biting. If the patient is nervous he can be given 3 gr (0.2 g) of sodium amylal before the treatment, while patients who suffer from rheumatoid arthritis with some stiffness of the joints have been given tubocurarine to produce muscular weakness so that the pull on the bones will not be so great. When the patient is held in the correct position a current is passed through his head by means of two electrodes, and a typical major epileptiform attack occurs. He is put back to bed, and for a time may be confused and complain that he cannot remember. These symptoms clear up in the course of a few hours and may recur temporarily when the next fit is given. Some authorities maintain that permanent memory disturbance and intellectual impairment result from this form of treatment, but this seems to be the case only when the treatment is given too frequently. The number of fits depends on the progress made, and in some cases an occasional fit as an out-patient keeps the patient going, whereas otherwise his condition would be chronic and mean a permanent stay in hospital.

Prefrontal Leucotomy

Moniz first used this operation on patients suffering from incurable mental disorders. After injecting alcohol into the subcortical white matter of the prefrontal lobes cores of white matter in the prefrontal areas were separated with a steel leucotome but not removed. Since Moniz first employed the method various techniques have been devised, it is obviously not practicable to describe the technique here, as the operation can be successfully carried out only by a neurosurgeon. Post-operative care and nursing are important, a careful check being kept on the pulse, respiration, and blood pressure for at least 48 hours. For restlessness $1\frac{1}{2}$ gr (0.1 g) of soluble phenobarbitone may be given intramuscularly, and 1 gr (65 mg) of codeine phosphate four-hourly may be used for the relief of headache. Morphine must on no account be given.

The operation, which should be performed only when all other methods of treatment have been tried and failed, has been carried out successfully on disturbed and noisy schizophrenic patients, thus making them more easily managed and rendering the nurses' task less irksome and difficult. In a limited number of cases such patients have been able to live outside hospital and in the care of relatives. In involutional and other long-standing depressive illnesses leucotomy has been successful, while experimental work on the value of the operation in antisocial mental defectives, post-encephalitics, etc., is still being carried out.

In the neuroses, such as obsessional and anxiety states—illnesses which can as completely incapacitate the individual as the psychoses—successful results have been reported. The tension and anxiety are relieved and the obsessional thinking, rumination, etc., although still present, are much less vivid and do not handicap the patient to the same extent as before operation. It is important before operation to inquire very fully into the patient's personality, as aggressiveness and other such traits causing antisocial conduct may become more pronounced after operation.

The intellectual capacity is said not to undergo any reduction. Obviously where the patient was previously doing a job for which a high degree of intelligence was not required the point is not important, but where such a high degree is required careful thought must be given as to the advisability of operation. The patient, however, may become less self-critical, more demanding, and hasty-tempered, with resulting conflict with his environment. The

mortality rate is low and usually death is due to haemorrhage, while a late complication may be the appearance of epileptic fits and status epilepticus.

Narco analysis Abreaction

It has long been recognized that an unpleasant traumatic experience is repressed from the conscious into the unconscious mind. The result of this repression leads in many cases to a gap in the memory, or fugue, which extends from a short time prior to the trauma to some time after it. The resultant loss of memory is a source of worry to the patient, as sometimes he wonders what happened during this period of amnesia, and he may think that he has committed a criminal act. Hypnosis and psychotherapy were formerly employed to try to re-establish this loss of memory, together with the unpleasant episode, and in many cases considerable time had to be spent before the psychiatrist was successful in bringing about a cure. During the war this type of hysterical reaction in which the patient went through a harrowing experience was common, and as it was necessary to try to restore the memory rapidly, sodium amylal, given intravenously, was first used. A dose of $7\frac{1}{2}$ gr (0.5 g) in 5 ml of water is given slowly at the rate of about 1 gr (65 mg) per minute, and when the patient has received about 5 gr (0.32 g) he becomes relaxed and in a state resembling that of drunkenness, in which he is garrulous and talkative. The patient's conversation is then led from the last thing he recollects before the incident until the actual incident itself is recalled and re-enacted. In many cases several sessions are necessary before the full incident is recounted, and during these sessions the patient relives the experience and a terrific amount of emotion is released. When it is considered that the patient has talked sufficiently at that session the injection of sodium amylal is completed, after which he sleeps for several hours. It might be argued that it is unwise to restore an unpleasant incident which is upsetting to the patient, but the loss of memory is productive of much more worry to him than a knowledge of the incident, which can be explained to him and be accepted in a reasonable light. This abreaction, or getting rid of pent-up emotion, has also been called "mental catharsis" or "emotional diarrhoea".

Various other drugs have been employed for this purpose—namely, thiopentone, hexobarbitone, and ether. The last named is now more commonly used than sodium amylal to produce abreaction. This form of treatment is also of value in peacetime in hysterical loss of memory and acute anxiety states where obviously some traumatic incident has been repressed.

Psychological Methods of Treatment

I do not propose to discuss at length the various techniques of psychological treatment, as the specialized forms such as psycho-analysis should be left to those specially trained in this type of treatment, while hypnosis, suggestion, and persuasion are constantly used as adjuncts to physical methods of treatment or by themselves.

The importance of suggestion is seen when a patient is admitted to hospital. When he enters the ward he should be made to feel the business-like atmosphere and air of confidence among the medical and nursing staff, rendering him hopeful about the outcome of his illness. This suggestion plays an important part in the whole hospital atmosphere, while the giving of medicines, even though they may be only placebos, can help in this way. Psychotherapy, such as detailed history-taking, the talking over of difficulties, discussion of home and other worries, must be used in every case. Group psychotherapy, where several patients meet and discuss their symptoms and difficulties collectively, is also of value.

Patients erect situations which they find difficult and which they are ordinarily unable to face this technique is called psychodrama. These methods of treatment allow every patient to receive treatment at the same time and help to develop team spirit also. In dealing with the psychological approach to the patient I should like to mention certain aspects which have been evolved as a result of our own experiences and which can be carried usefully into civilian life. At the outbreak of war men were called up for the Army and if medically fit were sent into various branches irrespective of their training in civilian life or degree of intelligence. As a result it was found that men who were possibly labourers and were dull intellectually were sent to workshops where skilled engineers were required, while skilled engineers were likely to find themselves doing labouring jobs in the Pioneer Corps. The result was that the man who had had no skilled training and was unable to do his job became anxious and worried about it and broke down, while the skilled man became "browned-off" and bored with the dull monotony of his job and also broke down because of the lack of opportunity for him to use his skill. This led psychiatrists and psychologists, with the co-operation of the appropriate Service authorities, to devise selection in the placing of recruits into jobs more in keeping with their knowledge and capabilities. When a man had no skilled trade or profession in civilian life he was tested by the psychologist from both the intellectual and the vocational point of view so that he might be trained along the lines for which he showed some natural aptitude or bent. In this way recruits with a tendency to artistic work might be employed in cartography or draughtsmanship, while no time would be wasted in training an intellectually poor man with little or no natural aptitude when he was obviously suited only for menial and labouring jobs. This personal selection proved of great value in preventing unnecessary breakdowns among Army personnel, and is now being used in civilian life in industry. It is important that the right job should be found for each type of person wherever possible. In addition, it was observed during the war that some men were able to shoulder responsibility up to a certain degree, but when promoted above this point were unable to cope with the added responsibility, and broke down if not allowed to revert to their previous rank. In civilian life the same thing applies—some people are able to rise only to a certain level and if promotion means added responsibility to which they cannot adapt themselves they must be content if they wish to lead normal useful and happy lives, with a lower income level than the man who can accept that responsibility. This point is dealt with in a little more detail later on.

Rehabilitation and Occupational Therapy

The treatment of the neurotic differs from that of the physically ill patient in that the former, except when undergoing special treatment, is not confined to bed and his day must be planned in some useful way for him if he is to be prevented from becoming bored and brooding over his troubles. For this purpose various adjuncts to the treatment already mentioned are provided in a neurosis centre. Physical training, varying from light to full, should be given daily to those who are physically fit for it. In many cases the neurotic has a poor posture, and the correction of this by physical training helps in restoring confidence. Occupational therapy must also be provided, and this can be divided into recreational, diversional, and vocational. The first consists in providing reasonable recreational activities in the form of indoor and outdoor games. In the nature of games it is wise to have inter-vara competitions, to provide healthy rivalry and stimulate team spirit.

Concerts, entertainments, and discussion groups are held, while recitals by well-known instrumentalists, who at the same time give talks about the instruments and the history of music, help to stimulate the patients' interest. Lecture discussions are held every week, all the lecturers being authorities on their subjects. Politics, geography, history, and other topics are discussed.

Diversional occupation consists in the making of various articles in the workshops. Among the types of occupation are rug-making, leather work, perspex work, making soft toys, carpentry, and gardening. The patients are allowed to choose the kind of work they wish to do, and when an article is completed they are allowed to purchase it at cost price. The accomplishment of making an article brings with it a sense of pride and helps to restore the loss of confidence from which most neurotics suffer. Lastly, the vocational type of occupation provides a means by which a patient who has no trade to go back to can be trained—for instance, in gardening or carpentry—and the foundation laid for him to begin a more thorough training that will help to rehabilitate him in the outside world. Patients are not dragooned into working, but are encouraged to do so, and they usually respond well.

It is important that neurotic patients should be allowed out of hospital to visit their homes, local cinema, etc., so that when the time comes to leave hospital the task of readaptation to social life will not be so difficult.

Industrial Neurosis Unit

An experiment that is being carried out at Sutton consists in the development of an industrial neurosis unit. One hundred beds for both sexes are being set aside to which neurotics who are misfits in industry can be admitted. For some considerable time it has been known that men and women go to employment exchanges almost weekly asking for new jobs as they are unable to cope with their present ones. Jobs are changed at very frequent intervals and for trifling reasons—namely, that the work is too noisy, the conditions under which they work are too hot or too cold, or they cannot tolerate the foreman. These people are to be referred to a psychiatric out-patient clinic for an opinion. If there is a psychiatric condition which requires treatment this will be dealt with by out-patient attendance if possible, otherwise the patients will be admitted to the industrial unit.

It is hoped that it will be possible to treat and "vet" such patients in the course of a few weeks and that a maximum stay of six weeks in hospital will be required. The patient will be tested by a psychologist to assess intelligence and to find out what his natural aptitudes are. A social worker will investigate his home conditions and attempt to straighten out any difficulties, while appropriate psychiatric treatment will be given for his condition.

Additional workshops are being supplied for the unit, and it is hoped to provide for hairdressing, tailoring, secretarial work, bricklaying, plastering, and interior decorating. These shops will be staffed by skilled instructors, each of whom can teach about 10 patients at any one time. It is also hoped to establish a liaison with local firms where hospital patients may be sent to work in an unpaid capacity for a few hours each day. This will help in vocational selection. A Government training centre will provide 20 vacancies a week for patients who are found to be suitable for teaching a particular trade, while a full-time disablement resettlement officer of the Ministry of Labour will be attached to the unit to help in placing the patients after discharge and to send reports to the patient's local employment exchange. After-care will in most cases be of

great importance, and a social worker will cover both the patient's home and employment after discharge.

This, briefly, is an outline of the scheme, and it is hoped that many patients who formerly helped to swell the ranks of the unemployed will be returned to work either in the open market or in sheltered employment.

Conclusion

There is no doubt that psychiatry is fast becoming, or has become, an important branch of social medicine. Adequate housing and education, the teaching of the individual how to enjoy his leisure time without becoming bored, and financial security are all important factors in promoting mental health and in preventing relapse of those who have recovered from mental ill-health. The removal of public prejudice against mental disease, and an attempt to make everyone appreciate that psychiatry is a scientific subject, are of paramount importance in the promotion of mental hygiene.

PENICILLIN IN THE TREATMENT OF DIPHTHERIA

BY

DAVID A LONG, MB, BS

Lecturer in Bacteriology London School of Hygiene and Tropical Medicine

Penicillin Sensitivity of *Corynebacterium diphtheriae*

In 1929 Fleming reported that a slightly purified extract of a broth culture of *Penicillium notatum* was active against the pyogenic cocci and rather less so against *Corynebacterium diphtheriae*. This observation was confirmed by Clutterbuck *et al* (1932) and by Chain *et al* (1940). Young and Mood (1945) tested six strains for penicillin sensitivity and found all to be inhibited by concentrations between 0.004 and 0.06 unit per ml. In contrast to this Ercoli, Lewis, and Moench (1945) found that over 1 unit per ml of penicillin was required to inhibit growth. Long (1946b) tested thirty strains and obtained sensitivities between 0.02 and 0.004 unit per ml. It is probable that the size of the inoculum used is an important factor in accounting for these differences, though even if an organism is resistant enough to require over 1 unit of penicillin per ml to inhibit growth the possibility of successful treatment is not excluded.

Experimental Work on Treatment in Guinea-pigs

Reports on the treatment of experimental diphtheria in guinea-pigs are conflicting, Young and Mood (1945) claiming that infection could be prevented by extremely small amounts of penicillin mixed with the inoculum, and cured by larger doses given as long as 23 hours after inoculation with a larger dose of culture. Ercoli, Lewis, and Moench (1945) on the other hand, state that penicillin had only a negligible action on the course of an infection following a small inoculum.

It would appear that there is not sufficient evidence on which to judge the effect of penicillin on artificially induced diphtheria in the guinea-pig, but even if the evidence were conclusive it is doubtful whether it would be safe to argue from guinea-pig to man. The degree of susceptibility and the lesion resulting from injection of culture in the guinea-pig are not comparable to the naturally occurring disease in man. Further, diphtheria in man is commonly complicated by secondary infection with haemolytic streptococci, Vincent's organisms, and mixed

anaerobes. All these organisms are markedly penicillin-sensitive and are almost invariably present in the disease, though the haemolytic streptococcus is less common than the others.

Penicillin-treated Cases in the Literature

Symons (1945) reported the case of a boy of 13 years who received antitoxin and sulphonamides on the second day of the disease. One day later, as a result of the development of bull neck and spreading of the membrane, penicillin was administered, 24,000 units being given three-hourly. This was followed by the membrane "separating, disintegrating, and almost disappearing within 24 hours." *C. diphtheriae gravis* and haemolytic streptococci were obtained from swabs before treatment.

Archer (1945) describes the dramatic improvement in the local condition of a patient with "mixed KLB, haemolytic streptococci, and Vincent's infection." Diphtheria antitoxin and antistreptococcal serum had been given previously without effect. Christie and Preston (1946) refer to two patients both with mixed *C. diphtheriae intermedius* and haemolytic streptococcal infections. Case 1, aged 15 years, had severe pharyngeal diphtheria with a bull-neck. The day of the disease is not given, nor is the state of activity of the membrane. He was treated with antitoxin and a sulphonamide on admission, three days later a petechial rash appeared, and systemic penicillin (100,000 units a day) with an hourly throat spray (500 units per ml) was started. The throat had almost completely cleared in another two days. Case 2, aged 17, had severe pharyngeal diphtheria of "not more than three days' standing." On admission the patient was treated with antitoxin and penicillin as in the previous case. The membrane separated in two days, though the general condition remained unchanged. Death occurred from heart failure, preceded by immobility of the palate.

Dodds (1946) reported 13 cases treated with penicillin and antitoxin, and 13 controls treated with antitoxin alone. *C. diphtheriae gravis* is stated to have been present in a "high proportion" of these cases, though exact figures are not given, neither is the presence or absence of secondary infection noted. 200,000 units of penicillin were administered daily for two days, followed by 100,000 units daily for three to six days. The conclusions reached were that penicillin "appeared to have been in some degree beneficial in most cases treated," though it "seemed to have little effect on the rate of clearance of the membrane." Symons (1946) reported a further case from which virulent diphtheria bacilli were not isolated.

De, Chatterjee, and Ganguli (1947) describe the successful treatment of 27 Indian children alleged to be suffering from diphtheria, penicillin being administered by three-hourly injections of 10,000 units. Antitoxin was withheld, since the work was undertaken "to ascertain whether the drug can be used in the place of serum," "the risk being minimized by selecting early cases, under the assumption that the child can destroy and/or eliminate a certain amount of diphtheria toxin." Of the 27 cases treated 11 are described as bacteriologically negative, in the remainder the organisms appear to have been identified on morphology alone. In view of the unusually high fever (10 of the patients had temperatures between 102 and 104° F (38.9 and 40° C)) it is unfortunate that no indication is given of the presence or absence of secondary infection and, in particular, of haemolytic streptococci. Their cases are classified into four groups. Group I early cases, bacteriologically positive. Group II early cases, bacteriologically negative but clinically diagnosed as classical diphtheria. Group III moderately severe cases, bacteriologically

spite of the fact that it was markedly penicillin-sensitive. This suggests that the dosage was too low. The strain of *C. diphtheriae gravis* was inhibited by 0.004 unit of penicillin.

Further Cases—Three further cases have been treated. All were mild and all received one million units of penicillin a day for three days, and in none was I able to demonstrate diphtheria bacilli after the first day's treatment.

Discussion and Conclusions

Though there is agreement that *C. diphtheriae* is penicillin-sensitive, considerable disagreement exists as to the degree of sensitivity recorded. A possible explanation is the absence of any standard technique for the estimation of sensitivity, and in particular of the size of the inoculum.

The experimental work in animals has produced conflicting results, so that there is little evidence on which to judge the possibility of effective treatment in man.

An attempt has been made to review all the cases of penicillin-treated diphtheria that have been described in the literature at the time of writing. In this country no case of diphtheria without secondary infection appears to have responded to treatment in a convincing fashion. By far the most important observations on this subject are those of Karelitz *et al.*, who, in spite of relatively large dosage (160,000–240,000 units a day), failed to observe any increase in rate of clearance of the membrane or any reduction in the incidence of toxic complications. The value of their report is impaired by their failure to use tellurite media and penicillinase for culture purposes, if they had done so their figures for the persistence of diphtheria bacilli would probably have been from 10 to 30% higher.

The most valuable criterion on which to judge the response to penicillin treatment would appear to be the time taken for *C. diphtheriae* to be eliminated from the lesions, thus excluding the effect of secondary infection. The dose of penicillin employed might reasonably be supposed to be that which reduces this time to the minimum.

Evidence is presented that *C. diphtheriae* can be eliminated in under 24 hours in severe cases of diphtheria with a dosage of 1,000,000 units a day. Though a smaller dose than this would probably be inadequate, a larger dose might be even more effective.

Summary

The available experimental and clinical evidence on the penicillin treatment of diphtheria is reviewed.

Experimental and clinical evidence is brought forward to show that it is possible to remove diphtheria bacilli from the upper respiratory tract within 24 hours.

A plea is made for larger dosage, at least 1,000,000 units a day would appear to be desirable in severe cases.

The value of penicillin is particularly striking in the presence of secondary infection.

The importance of early adequate antitoxin administration is stressed.

SPLINTS FOR FRACTURED NOSES

BY

MICHAEL C. OLDFIELD, MBE
 D.M., M.Ch. Oxon., F.R.C.S.

AND

W. R. ROBERTS, M.D.S., H.D.D.

Fractures of the nose are common injuries, but their early treatment is often unsatisfactory because displacement is obscured by haematoma and oedema. If telescoping of the septum does not obstruct the airway and there is no lateral deviation or depression of the bridge-line, no active surgical treatment is required. If any or all of these displacements have occurred, early treatment by the classical Gillies-Kilner (1929) technique of disimpaction and reduction yields excellent results with a minimum of discomfort to the patient. Should the displacement be missed in the early stages serious disability and disfigurement result which can be put right only by more extensive procedures such as nasal refracture or bone-grafting (Oldfield, 1944).

After reduction of a recently fractured nose a simple type of splint is required such as a "cellona slab" (Fig. 1).

FIG. 1

FIG. 2

FIG. 1—A "cellona slab" used for splinting a recently fractured nose after reduction.

FIG. 2—A Saffian brace.

a cellulose splint reinforced by a moulded lead plate, or a Saffian brace (Fig. 2), all of which serve to hold the nose in the correct position until union occurs in the correct alignment. This usually takes place in a very short time. If the bridge-line has been depressed, the "St. Louis method" is indicated (Fig. 3). Nasal refracture is required.

FIG. 3

FIG. 4

FIG. 3—"St. Louis method." Two lateral acrylic struts held in position by two through and through mattress sutures.

FIG. 4—Nasal splint in position.

When the nose has been allowed to unite in malposition Even if over-correction has been attained and a wedge of bone removed from the convex side there is always a tendency for the nose to slip back into malposition unless fixed by a rigid splint for a considerable period

A plaster head-cap is notoriously inefficient as a fixed base for facial splintage, but a dental-cap splint attached to the maxillary teeth gives an excellent base for rigid fixation of a nasal splint The splint described below has the added practical advantage that each lateral element can be adjusted in three planes and pressure can be applied wherever it is required The patient does not find it uncomfortable to wear, as no head-cap or straps are necessary It requires the close co-operation of a dental colleague for the fixation of the cap splints and at least four sound maxillary teeth for efficient anchorage (Fig 4)

Construction of the Splint (Fig 5)—(A) One brass plate for attaching the extraoral portion to a dental-cap splint The plate carries two arms of brass rod, gauge 4 mm, which are shaped to avoid the upper lip (B) Four modified Clouston-Walker universal joints for connecting A to C by means of straight brass rods (C) Two nasal supports, each consisting of a rubber-cushioned brass plate and arm Small nuts are threaded on to the ends of all the rods so as to prevent the apparatus from becoming disconnected when the universal joints are slackened

Fig 5—Diagram of nasal splint (For description, see text)

Method of Use—Stage 1 Preliminary to the operation for refracture and reduction, an impression is taken of the maxillary teeth and then a cast-metal cap splint is made and fixed in position on the patient Stage 2 At the end of the operation the nasal splint is attached to the dental-cap splint by means of two 6-B A screws The surgeon places the lateral supporting cushions in the desired position while an assistant locks all four universal joints with a spanner

The Société Internationale de Chirurgie will hold its twelfth Congress in London on Sept 14-20, with Dr L Mayer (Brussels) presiding Chairman of the English committee is Prof G Grey Turner, and the hon sec is Mr W S Wright The subjects to be discussed are as follows (1) The Operative Treatment of Fractures, by Prof R Danis (Brussels), (2) the Role of Penicillin in Surgical Practice, by Sir Alexander Fleming (London), (3) Recent Advances in Arteriography and Venography, by Prof R dos Santos (Lisbon) (4) Recent Advances in Vascular Surgery, by Prof R Leriche (Paris), (5) the Surgical Treatment of Pulmonary Stenosis, by Prof Blalock (Baltimore), (6) the Role of Vasodilatation in Arterial Diseases, by Dr J Diez (Buenos Aires), (7) the Results of Heparin in Surgery, by Dr Crafoord (Stockholm) (8) Skin Defects their Repair by Flaps and Free Skin Grafts, by Prof T Pomfret Kilner (Oxford) (9) Results of Early Operation in War Wounds of the Lungs, by Dr M Bastos Ansart (Barcelona), (10) Recent Progress in the Treatment of Burns, by a Russian surgeon Translated summaries of the papers will be circulated beforehand Members of the society do not pay an additional fee to attend the congress, but the subscription for the years 1939-47 must be paid The sum is 1,000 Belgian francs Members who have already paid a subscription at a higher rate will be credited with the extra amount, those who have not yet paid their subscription should send it to Dr Paul Lorthioir, 76, rue Faider, Brussels, or to the local treasurer if transfer of funds out of the country is not allowed Those intending to be present should notify Dr L Dejardin, General Secretary 141, rue Belliard, Brussels

Medical Memoranda

Temporary Hydronephrosis

The following case report seems to be interesting enough to merit publication

CASE REPORT

The patient, a corporal aged 25, was admitted to the British Military Hospital, Amriya, on Oct 9, 1946, with a history of urinary dysfunction for three days This consisted of dysuria, a poor stream, and frequency—he passed urine three times nightly He had no penile discharge, and the prostate was slightly enlarged but not tender Pus could not be forced into the external urinary meatus on prostatic massage Full physical examination elicited no further abnormality

Two days after entry into hospital his symptoms were unchanged, but the prostate was now very large and tender, prostatic massage producing a free flow of pus He developed a pyrexia of 101° F (38.3° C), which became intermittent A diagnosis of acute prostatitis was made Direct smears after prostatic massage were negative for organisms on repeated occasions Five midstream urine specimens contained many pus cells, but no other abnormality was found No organisms were grown Three 24 hour urine specimens were negative for acid fast bacilli, both on culture and on guinea pig inoculation The blood urea was 32 mg per 100 ml The white blood cells numbered 10,600 per c mm (polymorphs, 70.5%, lymphocytes, 19.5%, monocytes, 8%, eosinophils, 2%) A skiagram of the chest showed no evidence of a lung lesion

Fig 1—Pycelogram showing gross bilateral hydronephrosis and hydro-ureter

Seven days after the sudden marked prostatic enlargement an intra-venous pycelogram was performed This showed gross bilateral hydronephrosis and hydro-ureter (see Fig 1) He was started on a course of sulphadiazine and penicillin, 40 000 units three hourly, and this was continued for five days During this time his symptoms were unchanged, he still had an intermittent pyrexia and his prostate remained large and tender The chemotherapy produced no apparent result and was discontinued after five days On Oct 28 the prostate was much smaller, the temperature fell and remained normal, and his urinary symptoms became less pronounced He still complained of slight pain on urinating, but his stream was good and he passed urine only once or twice nightly On Nov 11 he was symptom free and the prostate was normal in size A second intra-venous pycelogram showed a great reduction in the size of both renal pelves and well pointed calyces (see Fig 2)

Fig 2—Pycelogram, taken four weeks after Fig 1

We can conclude that the hydronephrosis developed in one week, as the enlargement of the prostate occurred quite suddenly on the third day after admission The pycelogram showing gross hydronephrosis and hydro-ureter made us think that these changes might be permanent It may not be generally appreciated that marked hydronephrosis may occur suddenly and can be reversible if the obstruction is removed early enough These facts are well illustrated by this case

NUTRITIVE VALUE OF FOODS

The Nation's Food. A Survey of Scientific Data. Edited for the Society of Chemical Industry (Food Group) by A. L. Bacharach M.A. F.R.I.C., and Theodore Rendle F.R.I.C. With an Introduction by Sir Joseph Barcroft, F.R.S. (Pp. 349 18s.) London: Society of Chemical Industry, 1946.

Bacharach writes on the relative values for human nutrition of wheat offals eaten as such by human beings and given to milch cows as follows: "But knowledge and understanding of the facts is essential to any nationally sound solution of the problem. In 1939 when Britain had to formulate a food policy, many of the facts discovered since the first world war were scattered throughout the literature, some were little known and others misreported. The Food Group of the Society of Chemical Industry held a series of meetings from 1940 to 1943 at which thirty-two scientists discussed the nutritive value of foods. The papers were published at the time in *Chemistry and Industry*, they have now been revised and collected in this book, and even those who have made a special study of the subject will find it most convenient. The foods considered are eggs, potatoes, other vegetables, cereals, and meat. It is useful to have readily available definite statements about, for example, the distribution of ascorbic acid in potatoes and the effects of peeling on the degree of retention of ascorbic acid. Those who have not had the opportunity to collect and file such data will find information here that is in no other book."

Subjects that the authors discuss and about which many specialists may know little include the effects of cooking on nutritive value and the variations in the composition of meat. It is interesting to learn how great the losses may be when eggs are poached, why potatoes turn black on cooking, and that the temperature inside boiled eggs and roast beef may be too low to kill pathogenic bacteria. The chapters on the biology of potatoes and of fish are interesting, particularly the former, where Dr. Salaman discusses the diseases of potatoes, on which he has done much work. Here we find the answer to the question "Why do we buy Scotch seed potatoes?" Food control is still with us: the facts collected in this book should help to solve its problems.

BOVINE TUBERCULOSIS IN MAN

Studies on the Risk of Infection with Bovine Tuberculosis to the Rural Population with Special Reference to Pulmonary Tuberculosis. By Jón Sigurdsson. (Pp. 250 15s.) Copenhagen: Einar Munksgaard, London: Geoffrey Cumberlege, Oxford University Press, 1945.

The studies of K. A. Jensen and his colleagues during the ten years or so before the war showed that in Denmark the distribution of tuberculosis of bovine origin in man corresponded fairly closely to that of tuberculosis in cattle. Following this lead Dr. J. Sigurdsson has investigated what part the bovine tubercle bacillus plays in the causation of pulmonary tuberculosis and how the organism gains access to the human respiratory system. Between 1932 and 1940 a total of 566 strains of tubercle bacilli from patients with pulmonary tuberculosis in different parts of Denmark were typed at the State Serum Institute, Copenhagen. Nearly all the patients were over 15 years of age and over half of them came from Ribe County in the west of Denmark. Ninety-one of the strains were of bovine and 475 of human type. Investigation of the patients' place of residence showed that 40.6% of those infected with the bovine type had lived during the previous two years in rural districts, 28.2% in urban and rural districts, and 3.6% in urban districts. When the history of contact with tuberculous cattle was inquired into it was found that of 67 rural patients infected with the bovine type 94% had been in contact with strongly tuberculous herds, 6% with herds containing healthy reactors, and none with only tuberculin-negative herds. The conclusion reached therefore is that pulmonary tuberculosis of bovine origin in man is essentially an occupational disease resulting from close contact with tuberculous cattle. The results of two

special surveys in country districts supported this view. The author provides evidence to show that infection occurred usually not by ingestion but by inhalation.

This is a most interesting and well documented monograph. It goes far towards clarifying the problem of the mode of infection of the human being with the bovine tubercle bacillus. [This monograph was also commented on in a leading article in the *Journal* of May 24. Ed. B.M.J.]

G. S. WILSON.

CLINICAL PSYCHOLOGY

Modern Clinical Psychology. By T. W. Richards, Ph.D. (Pp. 331 17s. 6d.) New York and London: McGraw Hill Publishing Co., Ltd., 1946.

This book is intended for non-medical psychologists. The author defines clinical psychology as the study of the behaviour of the individual, in contrast to general psychology, which covers the general behaviour of men and animals. He considers that the psychologist should study the normal behaviour and minor maladjustments of the individual, leaving greater disorders to the psychiatrist. However, since their interests must sometimes overlap, the psychologist should know something of mental and even physical disease. He indicates three fields of observation in studying the behaviour of the individual: (1) Motivation, which may be security, wealth, fame or individualization and freedom from social ties; (2) capacity, chiefly intellectual, which may be innately defective or obscured by emotional conflict; (3) control, by which the author means not the Hughlings Jackson concept of individual cortical control of lower impulses but the effect of environmental inhibitions on individual impulses and the efforts to avoid the impasse such as withdrawal of energy or of the whole personality, hysterical manifestations, and obsessive compulsive behaviour.

The rest of the book contains details of how the clinical psychologist may gain information and insight into the personality of his patient. The estimation of capacity necessitates various forms of intelligence test, and these are described. Motivation is related to aggressive drives and especially to sexual adaptation. The author stresses the ubiquity of the homosexual component, which may be expressed apart from overt genital behaviour. He refers briefly to the pervasions as distortions of heterosexual adjustment. In estimating 'control'—the influence of the environment—he relies on the Rorschach tests and claims that they allow the subject to display his reactions to the environment without the intervention of suggestions from the examiner. He also uses the "Minnesota Inventory"—a series of propositions presented to the subject who divides them into 'true and false'. In a chapter on pre-occupation and predisposition he considers the hereditary, constitutional and disease factors influencing the personality, and in a final chapter on readjustment briefly indicates the lines of treatment required—some degree of analysis though not necessarily with the most complete psychoanalytic technique.

The medical reader may ask whether the non-medical psychologist should undertake all this and further, whether the nearly normal subject requires such an elaborate investigation except for purposes of pure research. May not the psychologist be tempted to treat the more severe case? However, the medical psychologist will be interested to read Dr. Richards's clear exposition of methods of investigating the personality.

R. G. GORDON.

PROBABILITY IN MEDICINE

Whether Medicine: From Dogma to Science? By Antony Fidler, M.D. (Pp. 116 6s.) Edinburgh: Thomas Nelson and Sons.

In this little book the author attacks what he calls "causal medicine" and proposes that the "medicine of probability" be substituted for it. In the first part of the book he has no difficulty in demonstrating that the generally accepted idea of causes of disease is unacceptable to the philosopher and that what we take to be a cause is often no more than a deduction from certain 'sense-data'. For example, because insulin is obtained from the pancreas by a chemico-physical process it is a fallacy to conclude that insulin is produced by the gland *in vivo* and the fact that certain lesions follow the inoculation into a guinea pig of a fluid which cannot otherwise be demonstrated to contain bacteria does not conclusively prove that the

fluid contained tubercle bacilli. Many other investigators have made these and similar observations. He shows that medicine and its ancillary sciences are based not on what is proved but on what is probable, and since the estimation of probabilities is the function of the statistical method, we support Dr Fidler when he advocates the more frequent use of statistics in prognosis and therapeutics.

His enthusiasm for numbers leads him, however, to some curious conclusions. He appears to believe that the "medicine of probability" will supplant "orthodox" medicine, yet obviously its true function is to aid it. He expects that his statistical tables, when they are sufficiently elaborated, will enable the physician to use them for the prognosis of disease in the individual. "We imagine that with the development of the numerical scheme we shall be able to predict with a probability bordering on certainty that this particular individual will die within the first week, that that individual will live fifty-one weeks, whereas another will live four years and nine weeks, and so forth." He advises us also to reject the objective criteria of disease—admittedly inadequate though they are—and to substitute for them "the subjective feeling of the person concerned." "Health is a feeling of comfort and 'disease' a feeling of discomfort."

Now when we are accustomed to pay close attention to the patient's story this definition is good, but it is not sufficient. Are we to ignore the x-rayed lung lesion, the silent mitral stenosis and the unexpected up-going toe because our patient makes no complaint? Are we to ignore Freud's work and accept what the patient says at its face-value? Is the man not ill because he protests his well-being? Measurement is the basis of science and the statistical method is but an extension of it. In bidding us abandon the objective approach to our patients as materialistic, Dr Fidler would curb the growth of medical science.

D V HUBBLE

The period of six years which has elapsed since the issue of the fourth edition of L. B. AREY's *Developmental Anatomy* in 1940 and the publication of the new fifth edition (W. B. Saunders Company, 35s) has been marked by important additions to our knowledge of the early developmental stages in human and macaque monkey embryos. Brief descriptions of this work, which have been largely carried out by well-known American embryologists, have been incorporated in the present volume, and simplified reproductions of many of their illustrations are also included. Moreover, allusions have been made to much recent work which has been accomplished in connexion with the determination of sex, and the assumed equal division of distribution of genes which accompanies the splitting of chromosomes, and the bearing of this assumption on heredity. The hormonal actions and control of the anterior pituitary gland, ovarian follicles, and corpora lutea, and the interstitial cells of the testis, are also discussed in connexion with their relation to the reproductive cycle, the induction of ovulation, the functional development of the mammary glands during pregnancy, and also the development in both sexes of the sexual characters. Work on experimental embryology has also received due notice and is discussed in relation to the influence of environment upon growth and variations, induced by such factors as (1) mechanical force, (2) physico-chemical agents, (3) radiations, such as those of heat, x-rays, or ultra-violet rays, (4) chemical, through ionic changes. Considerable changes and improvements have been made in other sections of the book, more especially by the introduction of a large number of explanatory drawings, which make the study of what is sometimes regarded as a difficult subject easy and attractive for a beginner, as well as for more advanced students and medical practitioners.

Ophthalmic Literature a new journal published quarterly by the British Journal of Ophthalmology, Ltd., under the editorship of Sir Stewart Duke-Elder, is a welcome addition to the literature of ophthalmology. It is working in close association with the B.M.A. Abstracting Service. The editor suggests in the preface that ophthalmology has become too isolated a specialty in recent years, this journal should provide that wider background that ophthalmologists are seeking. Abstracts of papers on general medicine, surgery, and pathology that have an ophthalmological bearing will be printed and references included to the current literature in optics, physics, physiology, biochemistry, and so on. The present number opens with a review of penicillin in ophthalmology, characterizing its value as immense and on occasions revolutionary, and concluding with 3½ pages of references. There follow over 200 abstracts from the whole field of ophthalmology. The journal is an excellent production and the matter well displayed and printed.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

The 1946 Year Book of Urology By Oswald S. Lowsley, M.D., F.A.C.S. (Pp. 392, 21s.) London: H. K. Lewis, 1947.
A summary of recent advances in urology.

Management of Common Cardiac Conditions Edited by William G. Leaman, Jr., M.D., F.A.C.P. (Pp. 306, 24s.) London: J. B. Lippincott, 1946.

Subjects discussed include the penicillin treatment of subacute bacterial endocarditis, the medical treatment of hypertension, and psychosomatic aspects of cardiovascular disease.

Sinn und Gehalt der Sexuellen Pervertionen By Dr. M. Boss. (Pp. 130, 12 Swiss francs.) Berne: Hans Huber, 1947.
An investigation into the nature of sexual perversions, with case histories.

Die Bedeutung der Seelenkunde von Klages für Biologie und Medizin By Dr. E. Frauchiger. (Pp. 99, 6.80 Swiss francs.) Berne: Hans Huber, 1947.
An account of von Kries's conception of the soul in biology and medicine.

Die Blutweisskörper des Menschen By P.-D. Dr. med. F. Wührmann and Dr. Ing. Chem. Ch. Wunderly. (Pp. 354, 36 Swiss francs.) Basle: Benno Schwabe, 1947.
The blood proteins in man and their clinical significance.

Metallschädigung der Osteosynthesen By Dr. R. Nicolet. (Pp. 74, 8 Swiss francs.) Basle: Benno Schwabe, 1947.
A study of the damage that may be caused by the metals used in bone fixation.

Nucleic Acid Symposia of the Society for Experimental Biology No. 1 (Pp. 290, 35s.) Cambridge: University Press, 1947.
Papers on nucleic acid by various authors read at Cambridge in July, 1946.

Law Relating to Hospitals and Kindred Institutions By S. R. Speller, LL.B. (Pp. 399, 22s. 6d.) London: H. K. Lewis, 1947.
A textbook on hospital law for hospital administrators, with an introductory outline of English law.

Diseases of the Basal Ganglia and Subthalamic Nuclei By D. Denny Brown, M.D., F.R.C.P. Ed. by H. A. Christian, A.M., M.D., F.A.C.P. (12s. 6d.) Oxford: Geoffrey Cumberlege, 1947.
An account of diseases that result from disturbances of the structure and function of the basal ganglia and subthalamic nuclei.

Endocrine Function of the Hypophysis By H. B. Friedgood, M.D. Ed. by H. A. Christian, A.M., M.D., F.A.C.P. (25s.) Oxford: Geoffrey Cumberlege, 1947.
Describes the development, structure, and function of the hypophysis and its hormones.

Treponematosis By Ellis H. Hudson, M.D., D.T.M.H. Ed. by H. A. Christian, A.M., M.D., F.A.C.P. (12s. 6d.) Oxford: Geoffrey Cumberlege, 1947.
The main theme is that syphilis, yaws, and the 'aphiloids' are caused by the same species of treponeme.

Ulcer of the Stomach, Duodenum, and Jejunum By Ralph C. Brown, M.D. Ed. by H. A. Christian, A.M., M.D., F.A.C.P. (12s. 6d.) Oxford: Geoffrey Cumberlege, 1947.
A clinical account of peptic ulceration, with differential diagnosis and treatment.

Introduction to Surgery By V. A. Frintz, M.D. and H. D. Harvey, M.D. (Pp. 216, 12s. 6d.) Oxford: Geoffrey Cumberlege, 1947.
An elementary introduction to pathology, surgical technique and anaesthesia.

Essentials of Clinical Proctology By M. G. Spiermann, B.S., M.D. (Pp. 238, 21s.) London: William Heinemann, 1947.
Discusses the embryology, anatomy, surgery, and post-operative care related to proctology.

THE PSYCHOLOGY OF SKILL

The subject of human skill is of interest to the medical profession in two ways. First, one of the commonest results of disease and ill-health is an impairment of skill in the broader sense of that word, while the restoration of skill is one of the chief aims of the physician. Secondly, the practice of medicine is itself a supreme example of human skill, and consequently it is desirable that those who enter the profession should show an aptitude for acquiring that skill and that the instruction they receive should enable them to develop it. If we give the term its widest possible meaning, almost every activity of a living creature is essentially an act of skill. Between the simpler adaptive activities, such as respiration or digestion, and the highest types of dexterity exhibited by the professional man there is merely a difference of degree. But ordinarily when we talk of skilled actions we mean, as Prof F C Bartlett points out, much more than the mere "basic fact" that an appropriate muscular response is called forth by receptor stimulation. We mean "behaviour in which many receptor and effector functions are interlinked, all joined in the pursuit of some task which can be evaluated and even measured in its own right." Thus skilled behaviour usually implies behaviour, that has been acquired or developed by experience. For this reason the study of skill has formed one of the chief topics for research in modern psychology.

In his Oliver-Sharpey lectures, delivered at the Royal College of Physicians at the beginning of the year and printed elsewhere in this and in our previous issue, Prof Bartlett gives an admirable review of recent efforts to study and measure different forms of human skill. The investigations which he describes have for the most part been carried out in the Psychological Laboratory at Cambridge. They have been largely rendered possible by the assistance given by the Medical Research Council, by the Flying Personnel Research Committee of the Royal Air Force, and by the Ministry of Supply. Some of his most arresting and instructive examples are drawn from experiments carried out in the study of the skill required by pilots or bomb aimers. The ways in which this type of operational skill may be affected by undue stress, by neurotic predisposition, and even by temperamental idiosyncrasies, is further illuminated by the reports recently published by the Air Ministry,¹ and discussed in the leading article at page 891

of this issue. Perhaps the chief lesson to be learnt from these experimental studies is that in the past neither the purely physiological approach nor yet the purely psychological approach has proved adequate, progress has been most rapid where the two standpoints have been combined.

All skilled responses involve both grading and timing. Skill whether bodily or mental (and what is popularly called bodily skill is essentially mental in its nature), has "from the beginning the character of being in touch with demands which come from the outside world." Hence one of the most obvious methods for evaluating the efficiency of a skilled action would seem to be to measure the success with which it is graded to meet the specific needs of the external situation. But this, as Prof Bartlett rightly observes, is by no means enough: the timing of the component reactions is far more important. "If we could understand the simple timing mechanisms which the body and mind must be able to use and the way in which they work we should have got much further towards a measure of the degree or level of skill." Nearly one hundred years have passed since Donders first worked out the technique of measuring reaction times. Yet the investigation of reaction times by the classical method has thrown but little light on the nature of the reactions involved in skilled behaviour or on the problem of their measurement. Indeed, until recently, most of what we know of the acquisition of skill, and of the best method of measuring it, was due to the investigations of the educational psychologist working in the classroom, supplemented by studies on animals carried out partly in the laboratory and partly in the field.

On the loss of skill the most brilliant researches are still those initiated by Henry Head, and the experimental methods adopted by Head himself in his studies of aphasic, apraxic, and ataxic patients have formed a suggestive starting-point for many of the ingenious procedures worked out by Bartlett and his colleagues. Some of the conclusions that he has reached have a direct bearing on methods of treatment and re-education. One of the first signs of diminished skill is that the operator, instead of remaining calmly concentrated on his ultimate object, becomes conscious or even self-conscious about the methods he is employing. "there is an increased awareness of what the body is striving to do." Slowing down the action, instead of making it easier as is commonly supposed, often makes it harder. Thus, paradoxically, skill that is threatening to deteriorate can often be restored by an objective increase in the difficulty of the action. To forestall a deterioration an essential condition is a continuing but moderate degree of novelty—a novelty which is great enough to oppose both the peripheral processes of adaptation and the central tendencies to mechanization and yet not so great as to throw the whole process out of gear.

The industrial psychologist, adapting the devices of the educational and clinical psychologist to the problems of selection and training for industry, has still further added to our knowledge. Yet he also has been too greatly engrossed with what is commonly called "repetitive skill

¹ Air Publication 3139 *Psychological Disorders in Flying Personnel* H.M.S.O. 1947

In practical life, when we attempt to assess a man's efficiency, there are two thresholds with which we are really concerned the one is a measure of what the operator is able to do and the other a measure of what he treats as worth doing. Thus, what Lewin and his pupils have termed the "level of aspiration" may be quite as important as the actual level of success. These conclusions have been amply confirmed by a recent report² on work carried out during the war. This report of an "Expert Committee" is the subject of an annotation at page 892 of this issue. The assistance of psychologists in testing and assessing recruits for different types of aptitude and skill proved invaluable in all three Services. Their success has prompted the suggestion that similar methods might usefully be employed in selecting applicants for the Civil Service, for various university courses, and in particular for the medical profession. Such methods have been employed in the past in assessing entrants to the teaching profession, particularly at times when the number of applicants has been far in excess of the number of vacancies. In a paper³ published in our last Educational Number D. H. Smyth described the methods adopted by the Faculty of Medical Sciences at University College, in co-operation with the Department of Psychology, for selecting suitable candidates for the medical profession. The results would appear to agree with those obtained in studies on personnel selection in the Forces. What is called "intelligence"—that is, innate, general, cognitive ability—is the first essential to the acquisition of every form of higher skill. The more complex and the more varied the skill to be acquired, the higher is the intelligence needed to acquire it. Such tests, therefore, have at least a negative value, they indicate which of the applicants are unlikely to complete their courses successfully and to pass the requisite examinations. Tests of this kind will undoubtedly save wastage during the training period. But beyond this they can hardly profess to go. The detection of specialized aptitudes and the assessment of character or personality must be left in the last resort to a competent board of interviewers, and interviewing itself is a highly skilled technique. Above all, what has been found true in the Services will hold good of every profession. "selection and training are not distinct and separable functions, but successive stages in a single procedure."

THE PSYCHIATRY OF WARTIME FLYING

Most of us had some idea of the wartime strain imposed upon the crews of R.A.F. aircraft. We guessed at the high casualty rates, and we imagined the fear, discomfort, monotony, and fatigue which were the essence of so much of their work. Citations of the achievements of such leaders as Cheshire and Edwards gave some insight into the experiences of the members of operational crews, but our understanding was limited by the secrecy which veiled so many of the details of their activities.

The Medical Directorate of the Air Ministry have now published a comprehensive account¹ of the stresses to which air crews were subjected in all types and conditions of flying throughout the war, and the psychological effects of these stresses. "Air Publication 3139" contains two dozen long and thoughtful reports presented to the Air Ministry at different stages of the war. Most of them are detailed clinical and statistical studies of neuroses, with field surveys of their contributory causes carried out by Air Vice-Marshal Sir Charles Symonds and Wing Commander Denis Williams, but there are also statistical analyses of performance by Squadron-Leader D. D. Reid. The work had an urgent practical background and for the most part was concerned with the psychiatric difficulties of men already carrying out duties. There is only one report, though a long one, on the psychological and psychiatric aspects of personality testing and vocational selection.

The size of the problem is indicated by the number of men who had psychological disorders sufficiently severe to call for psychiatric investigation and treatment—nearly 3,000 a year in the last three years of the war. This represented an annual incidence of about 12% in operational bomber crews in the year 1942–3. This means that one in eight of all bomber crews who survived long enough to develop symptoms had them so severely that the squadron medical officer sought psychiatric advice. There seems to have been no pressure upon the medical officer to do this, for an interesting report on the place of the squadron medical officer in preventing neuroses suggests that many more men with psychogenic symptoms were successfully treated on the station than were referred to the psychiatrist. Indeed, a study of the statistical surveys seems to show that the prognosis for return to duty of those who did reach expert psychiatric care was not good, only a little over a third of these men ultimately resumed flying duties. This is no reflection on the psychiatrists, but rather the reverse. It is clear that many of these men were predisposed to breakdown in conditions of operational flying and as they had already shown inability to withstand the hazards of their duties their removal from them seems eminently sensible. There was a close linear relationship between the assessment of the degree of predisposition to neurosis as a response to flying duties and the likelihood of the man being removed from those duties, through failure to recover from the psychological disorder. The degree of predisposition was assessed on the basis of a life history obtained at one interview. The points which related most closely to an assessment of marked predisposition have been analysed in the report on vocational selection.

In other respects also the serving psychiatrist, who has been something of a whipping boy, particularly in the lay Press, comes out of this critical and factual analysis with distinction. Prof. Bradford Hill and Dr. Denis Williams scrutinized statistically the agreement between independent psychiatrists who carried out several assessments without knowledge of each others' findings. They show in over 500 cases that in most instances agreement was fairly close. For instance, there was agreement in 85% of cases as to

² Report of an Expert Committee on the Work of Psychologists and Psychiatrists in the Services. H.M.S.O. 1947.
³ British Medical Journal 1946 2 357.

¹ Psychological Disorders in Flying Personnel of the Royal Air Force from 1939–45. Air Ministry. Air Publication 3139. London: H.M.S.O. Pp. 344. 7s. 6d.

whether flying duties had or had not played a significant part in precipitating the illness. In only 2% of cases was there serious disagreement as to the degree of psychological stress experienced in flying, on the basis of a three-point scale. Incidentally, these specialists were hybrids—neuro-psychiatrists—for there was no sharp distinction between neurology and psychiatry such as was made in the Army and Navy. This detailed study of the psychiatric assessment of predisposition to neurosis also contains much interesting material on the personality traits which were found to handicap a man in flying.

In one important respect these collected reports command attention. The authors have presented a mass of psychiatric material, collected from unusually large groups by many psychiatrists, in an objective, and perhaps in some places, in a rather dry statistical manner. Where facts could not be recorded and subjected to statistical scrutiny opinions have been pooled, and whenever possible their validity has been tested. This rigid method of presentation must surely have had some influence in securing the acceptance of the findings by many practical critics in the R A F who, with a highly objective approach to the problems of air crews, would otherwise have rejected the psychiatric method. The serving officer has always been hostile to any theory unsupported by hard facts, but he must have been influenced in his management of aircrew by the evidence presented here. The statistical method has been extended in these reports by orthodox clinical psychiatric studies, and by descriptions of observations made in operational stations and on squadrons, where observation was reinforced by a synthesis of the statements and opinions of senior officers. The reports are in effect a detailed survey of the psychiatry of fear evoked in a highly specific set of circumstances, circumstances so uniform and primitive that the psychiatric situation is an unusually simple one. Because of this—except in the methods employed—the observations have little direct application to the problems of peace. On the other hand, they present a wealth of knowledge which cannot be accumulated in peacetime but which would have immediate application if men had to fly offensively again, whatever might be the conditions and circumstances in which they had to do so.

PSYCHOLOGY AND PSYCHIATRY IN THE SERVICES

In the early years of the war it was apparent to the authorities that both psychiatrists and psychologists had a considerable part to play in the organization of efficiently operating armed Forces. Psychiatrists were called on to treat men suffering from various forms of nervous and mental disorder and to weed out, either from smaller groups such as task forces or from the Service as a whole, those who were specially prone to nervous breakdown or were otherwise unlikely to contribute to operational efficiency. Psychologists were given duties in such fields as security, camouflage, education, and publicity, and had also to provide tests of intelligence and educability which would allow the most effective allocation of individuals. Both groups of specialists had important duties which were not strictly medical, and which involved close liaison with executive officers. It is not surprising that such a revolutionary innovation led to a good deal of criticism, and that at times both psychologists and psychia-

trists met with hostility and obstruction. Those least acquainted with these specialties were probably easiest to convince of their value. Psychiatrists found on the whole that they met with more criticism from medical than from executive officers. Psychologists met with more criticism from psychiatrists than from medical or executive officers. The pressing need for specialist advisory and other services on the one hand, and this widespread criticism on the other, led to the appointment of an expert committee to examine and report on the whole problem. Its report is now published,¹ and although it is "after the ball is over" the deliberations of the committee and preliminary knowledge of what its recommendations were likely to be must have greased the wheels of Service machinery at a relatively early stage. Now that the report has appeared it is likely to exercise a decisive influence on the future organization of psychological services of all kinds in the Armed Forces.

Approximately a quarter of the report deals with Service psychology and psychiatry under separate headings: their scope, Service applications, the training of staff, their use in the armed forces of other countries. Conclusions and recommendations follow, and the rest of the volume consists of a number of appendices. The conclusions and recommendations provide an emphatic vindication of the value of applied psychology and psychiatry in this field and a justification for their continuance. Perhaps the most important recommendation is that there should be a considerably greater degree of integration of psychology and psychiatry in the Navy, the Army, and the Air Force. It is suggested that there should be an inter-Service body consisting of the senior Service psychologists, and in psychiatry that there should be some recognized meeting-ground at which the senior Service psychiatrists could discuss common problems and make available to one another the procedures developed in each Service. Close contact should be maintained between field psychiatrists in the three Services, and a central co-ordinating and statistical section should be established for bringing the civilian Neurosis Centres of the Emergency Medical Services into closer contact with one another and with the corresponding Service departments. An interesting omission is that no recommendation is made that the work of psychologists should be done under the direction of psychiatrists.

These recommendations are of crucial importance. To take the field of psychology, work of great practical importance was done in fitting men into Service occupations where they would be most efficiently employed, and in defining the qualities and abilities demanded by these various occupations. As a result there was a much more efficient distribution of man-power within each of the Services. Perhaps even more important than this is the distribution of men between the Services, and implementation of the recommendations contained in this report would be a useful first step in this direction. It is also suggested that all officers should receive some training in the psychological aspects of their duties, and some of them a specialist training, that psychologists should be represented on the principal scientific and advisory committees, and that they should participate as observers in battle operations and exercises. Psychiatrists should, in collaboration with psychologists, contribute to appropriate aspects of selection, classification, training, mental hygiene, and the maintenance of morale; they should be employed in screening procedures, and psychiatric training should be given to both medical and combatant officers in these aspects of their duties.

¹ *Report of an Expert Committee on the Work of Psychologists and Psychiatrists in the Services* 1947. H M S O. Price 2s. net.

In criticism of the report it must be said that it is extremely indigestible and lacking in technical value. No attempt is made to give in precise and factual terms a description of the conditions encountered, the actions carried out, and the results observed. There is no discussion of methodological developments. The factual material embodied in the appendices is disproportionate, incomplete, and uncritical. For instance, the use of films for time and motion studies of squads of men at work, which was one of the most interesting applications of psychological methods made by the Army, receives scant appreciation and no description. The differences in the use made by the Army, the Navy, and the Air Force of psychological methods in training speak for themselves but are the subject of only brief comment. The association between the present crime wave and desertion from the Services is now publicly acknowledged, but no suggestion is made that psychological methods of personnel management might be more widely applied in serving units.

BACTERIAL WARFARE

If a third World War occurs it is likely to be even more unpleasant than the 1939-45 disturbance. What with rocket-propelled atomic bombs, radioactive sprays, and poison gases calculated to make mustard gas seem no more distressing than a slight overdose of sal volatile, the next war is hardly likely to see many survivors. To complete this tale of horror we are from time to time solemnly warned that bacterial warfare will be freely used.

The idea that infection can be deliberately spread by evilly disposed persons is not new. When Europe periodically suffered from outbreaks of bubonic plague perfectly innocent persons were almost invariably accused of spreading the disease by poisoning wells, an accusation to which, curiously enough, they often pleaded guilty. In the same way outbreaks of trypanosomiasis, cerebrospinal meningitis, and influenza in tropical Africa are generally attributed to the malignant witchcraft of some unfortunate man or woman. Europe, however, is no more civilized than Africa. Despite the various pacts and international conventions which have outlawed bacterial warfare, it would almost certainly have been used had the Nazi rulers of Germany been convinced that it would favour their grandiose aggression. It is now no secret that shortly before the beginning of the last war an enemy agent actually did attempt to gain possession of a virulent strain of yellow fever virus. In the autumn of 1939 Dr Goebbels, broadcasting from Munich, accused the British of attempting to introduce yellow fever into India by transporting infected mosquitoes from West Africa and liberating them from aeroplanes over Indian cities, the whole scheme being presided over by a high permanent official of the Foreign Office.

There has been so much uninstructed talk of the possibilities of bacterial warfare that a critical and well-documented discussion such as that provided by Rosebury, Kabat, and Boldt¹ is of considerable value. Bacterial warfare, including under that term the use of pathogenic protozoa and viruses, can obviously be directed not only against man himself but against his domestic animals and cultivated crops. The suitability of potential agents can be estimated by criteria such as their infectivity and virulence for the particular host against which the attack is directed, the availability and resistance of the causal agent, its means of transmission, ease of detection and epidemicity, the availability of methods of immunization and

specific treatment, and the possibility of what is called "retroactivity", in other words, the possibility that the infection may involve not only the attacked but also the attackers. Infectious agents to which a given population has never been exposed have obvious points in their favour. Several plant diseases pass this test and are considered eminently suitable for damaging an enemy's food supply, while insects such as the Colorado beetle might well be added to the list. A detailed study of human and animal infections serves to eliminate a considerable number of pathogenic organisms on the grounds that their infectivity is low, their control comparatively simple, or the knowledge available of their methods of spread too meagre. However, some 33 bacteria and viruses remain, among them being agents transmitted by water, air, and insects. Viruses are obviously prime favourites, for at present chemotherapeutic treatment is lacking, and, apart from vaccinia, vaccines are either not available or are manufactured only in quantities quite insufficient for mass immunization. Strains of bacteria rendered resistant both to penicillin and the sulphonamides might be difficult to deal with since it would take some little time to discover that the organisms really were drug-fast. Among the virus diseases which might possibly be used are yellow fever, psittacosis, Rift Valley fever, louping-ill, equine encephalomyelitis, foot-and-mouth disease, rinderpest, fowl plague, and Newcastle disease, while bacterial infections which might be employed include pneumonic plague, brucella infections, anthrax, botulism, glanders, melioidosis, and tularaemia. The causal agent of the last infection would doubtless have to be rendered resistant to streptomycin. Unfortunately these diseases do not exhaust the possibilities, for dried suspensions of rickettsiae could easily be produced in large amounts, while in the Tropics the introduction of an efficient malarial vector, such as *Anopheles gambiae*, into a country where malaria is but mildly endemic might easily give rise, as it did in Brazil, to a devastating malarial epidemic. Biting flies, such as *Stomoxys* which can convey trypanosomes directly by their bites, might well serve to destroy cattle in large numbers by infecting them with *Trypanosoma congolense*. Special attention is directed by Rosebury and his colleagues to those viruses which have given rise to infections among laboratory workers, yellow fever, for instance, caused a large number of such infections before an efficient means of immunization was developed, for the virus can readily pass through the nasal mucosa or conjunctiva and through the apparently intact skin.

It seems doubtful whether at the moment bacterial warfare could be directed against man on a nation-wide scale, but it could well be used against particular cities or isolated strong points during the course of hostilities, and the occurrence of strange epidemics or epizootics before an outbreak of war might so disorganize a people and lower their morale that their will to resist aggression would be seriously impaired.

For bacterial warfare to be an efficient aggressive weapon far more must be known of the effective dose or concentration of different agents when sprayed from the air. Also much more knowledge would be required of the infectivity of finely divided lyophilized bacteria and viruses and of their survival after dissemination from aircraft, with and without smokes and poison gases. Similarly the capacity of spore-forming bacteria to withstand dissemination in explosive projectiles is still unknown. Answers to these and similar questions, however, could readily be obtained.

The control of bacterial warfare by international agreement is even more difficult than the control of air

bombs, it may, in fact, be regarded as impossible. Much, however, might be done to guard against bacterial warfare by intensifying the search for chemotherapeutic agents active against viruses and by the construction of masks which can hold back even the smallest viruses. It also seems somewhat ludicrous that most of the laboratories capable of turning out vaccines on a large scale should be situated in some of the most vulnerable areas in this far too vulnerable island. There is one ray of hope. The factors governing the epidemic spread of a particular organism are as yet but little known. To initiate an epidemic at a particular moment in a given population would be a unique experiment far less certain in its results than the explosion of a mere atomic bomb. In the past attempts to start epizootics among animals have not been very successful. Pasteur,² it will be remembered, produced an epizootic among rabbits with the bacillus of fowl cholera, but a more recent attempt to destroy rabbits in Australia with the virus myxomatosis, a far more specific and deadly pathogen, was completely unsuccessful.

RADIOACTIVE ISOTOPES AGAIN

The Medical Research Council has shown both wisdom and foresight in inviting Prof. Robley D. Evans, of the Massachusetts Institute of Technology, to visit this country. Several British medical physicists^{3,4} were fortunate enough to share in Toronto in some of the wartime applications of the new radioactive isotopes to biological and medical research, and with Sir James Chadwick,⁵ whose interests are not primarily medical, they have since done their best to convey to others some idea of the possibilities which have been opened up by these new techniques. No British physicist, however, would claim to equal either the length or variety of the combined experience of Prof. Evans and Dr. J. G. Hamilton, of the Radiation Laboratory, Berkeley, California, who accompanies him. Prof. Evans combines in rare degree the qualities of modesty and enthusiasm, and he has allowed himself to be worked as hard as the most exacting and appreciative of hosts could have desired. The most valuable results of such a visit must be personal and intangible, for, in the application of any new technique, however simple in principle, there are inevitably points of detail and procedure which can be satisfactorily communicated only by word of mouth. Such contributions cannot be readily measured or assessed, but at the conclusion of his lecture at the Royal Institution last week he received an ovation of a kind which can have been given to few others in that historic theatre.

Four points may be picked out from his address. The first is an illustration, by graphic simile, of the power of the method. If all the atoms in a tumbler of water could be labelled, as with radioactivity, and then tipped into the sea and there left to distribute themselves about the oceans, the number of atoms so marked which one might later expect to recover in any random tumblerful of sea-water from any part of the world would be 5,000. The illustration was not claimed to be original, but it brings out, as many more lengthy explanations might fail to do, why it is that such small quantities of radioactive substances will go such a long way in research. The second point, which is connected with the first, is that human subjects have little to fear from such experiments knowledgeably conducted. After seven years of research on dogs, and some 300 experiments on human beings, the safety factor is

regarded as sufficiently established. Moreover, it has been algebraically expressed in a simple formula which with knowledge of the necessary physical constants, can be applied to any particular radio isotope. Alternatively, it may be said that an additional intensity of radiation equivalent to one-half of the normal cosmic ray intensity at sea-level, to which the body is in any case permanently exposed, is enough for research purposes.

The third point is one of method and equipment. In describing in some detail the now classic investigation of the efficacy of different preservatives of stored blood and the activity of such blood after transfusion,^{5,6} which Sir James Chadwick has already made familiar in general terms, Prof. Evans must have astonished many by his account of the extent to which mechanization and standardization of procedure have been carried. In a suitably equipped laboratory it is possible to place two dozen specimens for radioactive determination on a mechanically operated turntable, to indicate on a series of punched cards the percentage accuracy to which each is to be assayed, and then leave the machine to "count" for periods suitable to each, and work out and record in permanent form the numerical answers. Two trained assistants can prepare and put through more than two hundred samples during an eight-hour day. The lesson is not one which the Medical Research Council is likely to ignore. The number and complexity of possible investigations is so great, using these new methods, and the numerical computation which may be necessary so considerable, that the saving of time of responsible investigators, and the virtual ensurance of standardized procedures, must in themselves make an important contribution to success.

Finally, Prof. Evans proceeded some little way beyond the published record in describing the results which have been obtained in the treatment of Graves's disease, first with the original "12-hours" radio-iodine, and later with the more convenient and stable "8-days" variety. Using the former, 65 cases have been treated, of which 27 have been published.⁷ With the latter a further 29 have so far been treated. Results are described as uniformly encouraging, with no unfavourable results at any stage. Moreover, the hyperthyroid activity of cases showing only a transient response to thiouracil has been reduced to a normal level by radio-iodine, and so continued without subsequent relapse over considerable periods. By comparison with the results of partial thyroidectomy the return to normality is relatively slow, and biopsy has been found of value as a routine procedure. The therapeutic case for radio-iodine has clearly been strengthened by further experience, notwithstanding, with the possible exception of lympho-sarcoma, that the opposite has been the case with radio-phosphorus.⁸ It may be recalled that some 415 artificial radio isotopes are now known, including at least one for each of the chemical elements, and, like others whose views command respect, Prof. Evans has left no doubt that their most valuable contribution is likely to be in research.

The generous donor who endowed the Commonwealth Travelling Professorship in Medicine announced at the Royal College of Surgeons of England last November is Mr. Arthur Sims, a prominent New Zealand industrialist with commercial interests in this country. Sir Hugh Cairns, Nuffield Professor of Surgery in the University of Oxford and a member of the Council of the Royal College of Surgeons of England, has been unanimously elected the first Arthur Sims Travelling Professor.

INTERNATIONAL CONFERENCE OF PHYSICIANS

The opening session of an International Conference of Physicians will be held at the Royal College of Physicians of London (Pall Mall East, S.W.) on Monday, Sept 8, at 11 a.m., and the conference will continue daily at various institutions and hospitals in London until Friday, Sept 12. In addition to the scientific programme, outlined below, a social programme, including a Government luncheon, a banquet in the Guildhall and a reception at the Royal College of Physicians of London is being arranged.

The organizing secretary of the conference is Dr G B Mitchell Heggis, FRCP, to whom applications for admission, which is confined to medical practitioners and is by invitation only, must be made, care of the Royal College of Physicians of London.

Scientific Programme

The conference has been arranged in eight sections, and the subjects for discussion and the names of the speakers are as follows

SECTION OF CARDIOLOGY

President Sir Maurice Cassidy *Secretary* Dr K Shirley Smith, 122, Harley Street, London, W1

Sept 9—Surgery of Congenital Heart Disease (with Section of Paediatrics), Dr Helen Taussig (U.S.A.), Dr C Crafoord (Sweden), Dr J W Brown (Britain), Dr A R Gilchrist (Britain), Mr O S Tubbs (Britain), Mr I Holmes Sellors (Britain)

Sept 10—Pulmonary Heart Failure (with Section of Disorders of the Chest), Dr J McMichael (Britain), Dr P H Wood (Britain), The Clinical Value of Chest Leads, Dr F Wilson (U.S.A.), Dr C W Bain (Britain)

Sept 11—The Use of Phonocardiogram in Clinical Cardiology, Dr William Evans (Britain)

Sept 12—Repetitive Paroxysmal Tachycardia, Dr J Parkinson (Britain), Dr C Papp (Britain), Sympathectomy for Hypertension, Preliminary Experiences, Dr G Bourne (Britain), Tomography in the Study of Cardiovascular Disease, Dr J H Wright (Britain), Dr E Tisceno (Britain)

SECTION OF DISORDERS OF THE CHEST

President Sir Robert Young *Secretary* Dr J G Scadding, Brompton Hospital, London, S.W.3

Sept 9—Transient Pulmonary Infiltrations, Prof W Löffler (Switzerland), Dr J L Livingstone (Britain)

Sept 10—Pulmonary Heart Failure—Acute and Chronic (with Section of Cardiology) Dr W D W Brooks (Britain)

Sept 11—Sarcoidosis (with Section of Dermatology), Dr C Hoyle (Britain), Dr C Cameron (Britain)

Sept 12—BCG Vaccination (with Sections of Social Medicine and Paediatrics), Dr J Heimbeck (Norway), Dr W H Tytler (Britain)

SECTION OF DERMATOLOGY

President Sir Archibald Gray *Secretary* Dr M Sydney Thomson, 106, Harley Street, London, W1

Sept 9—Vitamin D in the Treatment of Cutaneous Tuberculosis Dr J Chirpy (France), Dr G B Dowling (Britain), Dr S Lomholt (Denmark)

Sept 10—Clinical Meeting

Sept 11—Sarcoidosis (with Section of Disorders of the Chest), Prof L M Pautrier (France), Prof H Haxthausen (Denmark), Dr A H T Robb-Smith (Britain), Dr W Freudenthal (Britain)

Sept 12—Scurvy and Pediculosis, Dr P G Stock (Britain), Dr K Mellanby (Britain), Dr G H Percival (Britain), Dr P A Buxton (Britain)

SECTION OF NEUROLOGY

President Dr Gordon M Holmes *Secretary* Dr Macdonald Critchley, National Hospital, Queen Square, London, W.C.1

Sept 9—Malnutrition of the Nervous System, Dr W Russell Bruin (Britain), Prof J R Marrack (Britain), Dr M A Ruggs Gunn (Britain), Mr T Keith Lyle (Britain), Dr F E Posthumus Meyjes (Holland)

Sept 10—The Role of the Pyramidal System in Movement, Dr F M R Walshe (Britain), Dr E G T Liddell (Britain), Prof J A Barre (France), Dr Ludo van Bogaert (Belgium), Prof Mogens Fog (Denmark), Dr P van Gehuchten (Belgium)

Sept 11—Spinal Fluid and Cerebral Fluid—A Comparison Prof M Alajouanine (France), Altered Melody of Language (Accent) in Extrapyramidal Lesions and in Aphasia, Dr G H Monrad Krohn (Norway), Autodermography, Dr R Ceray (Czechoslovakia), Maternal child Incompatibility Problem in Relation to the Nervous Sequelae of Haemolytic Disease, Prof D F Cappel (Britain), Pathological Anatomy of Kernicterus, Dr J G

Greenfield (Britain), Operative Treatment of Myasthenia Gravis, Mr Geoffrey Keynes (Britain), The Use of DFP in Myasthenia Gravis, Dr Andrew Wilson (Britain)

Sept 12—The Functions and Connexions of the Frontal Lobes (with Section of Psychiatry), Dr W Ritchie Russell (Britain), Prof W E Le Gros Clark (Britain), Prof K Henner (Czechoslovakia), Dr G de Morsier (Switzerland)

SECTION OF PAEDIATRICS

President Sir Leonard Parsons *Secretary* Dr R C Lightwood, 86, Brook Street, Grosvenor Square, London, W1

Sept 9—Surgery of Congenital Heart Disease (with Section of Cardiology)

Sept 10—Haemolytic Anaemia, Dr S van Creveld (Holland), Dr I A B Cathie (Britain), Cathepsine as a Gastric Enzyme, Prof E Freudenberg (Switzerland), Steatorrhoea, Prof A C Frazer (Britain), Amino acids in the Feeding of Infants, Dr Rothe Meyer (Denmark), Dr J M Smellie (Britain)

Sept 12—BCG Vaccination (with Sections of Social Medicine and Disorders of the Chest), Prof A Wallgren (Sweden)

SECTION OF PSYCHIATRY

President Dr Bernard Hart *Secretary* Dr R D Curran, 6, Devonshire Place, London, W1

Sept 9—Genetics in Relation to Mental Deficiency, Dr J A Fraser Roberts (Britain), Genetics in Relation to Mental Disorders, Dr Eliot Slater (Britain), Dr F J Kallman (U.S.A.), Prof T Sjogren (Sweden)

Sept 10—Psychodynamics of Depression, Dr T A Munro (Britain), Dr W Clifford Scott (Britain)

Sept 11—Social Surveys (with Section of Social Medicine), Prof E Stromgren (Denmark), Dr E O Lewis (Britain)

Sept 12—The Functions and Connexions of the Frontal Lobes (with Section of Neurology), Dr G Rylander (Sweden), Dr W Mayer Gross (Britain)

SECTION OF SOCIAL MEDICINE

President Sir Wilson Jameson *Secretary* Dr J A Charles, Hillside House, Stanley, Co Durham

Sept 9—Care of the Aged and Infirm, Sir Ernest Rock Carling (Britain), Dr A Hojer (Sweden), Dr J Frandsen (Denmark)

Sept 10—Social Medicine in the Curriculum, Dr Jon B Grant (U.S.A.), Prof J A Ryle (Britain), Prof J M Mackintosh (Britain), Prof Axel Strom (Norway)

Sept 11—Social Surveys (with Section of Psychiatry), Dr C P Blacker (Britain)

Sept 12—BCG Vaccination (with Sections of Disorders of the Chest and Paediatrics), Prof G S Wilson (Britain)

SECTION OF GENERAL MEDICINE

President Lord Moran *Secretaries* Prof G W Pickering Ninnings, Denham Lane, Chalfont St Peter, Bucks, Dr M L Rosenheim, University College Hospital, Gower Street, London, W.C.1

Discussions are being arranged on the following subjects

Sept 8—Penicillin

Sept 11—Infective Hepatitis

Sept 12—Pain

BIRTHDAY HONOURS

The names of the following members of the medical profession were included in a Birthday Honours List published in *Supplements* to the *London Gazette* on June 12

Privy Counsellor

The Hon Sir GODFREY MARTIN HUGGINS KCMG CH, FRCS Prime Minister of Southern Rhodesia since 1934

K.C.B. (Military Division)

Surgeon Vice-Admiral HENRY ST CLAIR COLSON CB, CBE MB, BS, RN

K.C.V.O.

Sir HUGH LETT Bt, CBE, DCL, MB, FRCS President of the British Medical Association

Surgeon Rear-Admiral HENRY ELLIS YEO WHITE CVO, OBE, MD, FRCS Ed, RN Honorary Surgeon to the King

Knighthood

WILLIAM NORWOOD EAST MD, FRCP For services to the study of criminal psychology

DAVID KENNEDY HENDERSON MD, FRCP, FRFPS Professor of Psychiatry in the University of Edinburgh

ERNEST LAURENCE KENWAY MD DSc FRS, FRCP
Emeritus Professor of Experimental Pathology in the University of
London. Lately Director of the Chester Beatty Research Institute
of the Royal Cancer Hospital London

ALEXANDER McCALL MD For public services
ARCHIBALD HECTOR MCINDOE CBE, MS FRCS FACS
Civilian Consultant in Plastic Surgery to the Royal Air Force
Colonel GEORGE REID McROBERT CIE, MD, FRCP, IMS
Inspector General of Civil Hospitals, Bihar. Lately Professor of
Medicine, Madras Medical College, and Physician, Madras General
Hospital

THOMAS WILLIAM MEAGHER MB, BS Lord Mayor of the City
of Perth Western Australia, 1939-45 For public services
ROBERT ARTHUR YOUNG CBE, MD, FRCP Consulting
Physician, Middlesex and Brompton Hospitals

C B (Military Division)

Major General WILLIAM FOOT MC MB, BCh, late AMS
Honorary Physician to the King

C.M.G

JOHN MALCOLM MD Emeritus Professor of Physiology in the
University of Otago, New Zealand For services to the medical
profession

Colonel PHILIP GRAHAM STOCK CB, CBE, MB, FRCP
Medical Officer, Ministry of Health

C.I.E

Colonel LLOYD KIRWOOD LEGER OBE, MRCS, LRCP,
IMS Inspector General of Civil Hospitals and Director of Public
Health, Central Provinces and Berar

C.V.O

GEOFFREY SYDNEY TOOO OBE, MB, FRCP Medical Super-
intendent, King Edward VII Sanatorium, Midhurst Sussex

C.B.E (Military Division)

Temporary Surgeon Captain ROBERT GREGORY HENDERSON MD,
RNVR

C.B.E (Civil Division)

GEORGE LINDOR BROWN MB, ChB, FRS For services to
medical research in the Royal Navy

HENRY ANSTEY COOKSON MB, FRCP Ed, FRCS Ed For
public services in the County of Durham

ERIC WILFRED FISH MD DSc, DDS Honorary Dental
Surgeon, St Mary's Hospital, London, W

CONRAD TRELAWNEY FITZGERALD MD Medical Health Officer
for the Department of Public Health and Welfare, Trinity East,
Newfoundland

JAMES ANDREW GUNN DM, DSc FRCP Chairman, British
Pharmacopocia Commission Professor of Therapeutics in the
University of Oxford and Director of the Nuffield Institute for
Medical Research

SAMUEL THOMPSON IRWIN MCh Belf, FRCS Ed Chairman,
Northern Ireland Medical War Committee

ALOWYN BROCKWAY STOKES BM, BCh Lately Member of
National Advisory Council on the Employment of the Disabled

KHONG KAM TAK MBE, MB, BCh For public services in
the Malayan Union

O.B.E (Military Division)

Surgeon Commander EDWARD WILLIAM BINGHAM MB, BCh
RN

Lieutenant Colonel (Acting) CHARLES DAVIO BRUCE MB, ChB
RAMC

Lieutenant Colonel FREDERICK GRACE SMITH MBE, ED
Officer Commanding Ceylon Medical Corps

O.B.E (Civil Division)

VERNON FITZCLARENCE ANDERSON MD, Colonial Medical
Service Senior Medical Officer, British Honduras

Major HUBERT JOSEPH CURRAN MB, BCh, IMS Principal
Medical School Darbhanga Bihar

CATHERINE HARROWER MB, ChB Member of the Glasgow
Burg Insurance Committee

DAVID WINN HOOGLASS LMSSA, Colonial Medical Service
Lately Principal of the Central Medical School, Suva, Fiji

NORMAN HOWARD-JONES MRCS, LRCP Director, Medical
Department, British Council

Lieutenant Colonel ROBERT KELSALL DSO MD Chairman
High Wycombe Medical Board

DAVID JAMES MASTERTON MacKENZIE MBE MB ChB
Director of Medical Services, Bechuanaland Protectorate

WILFRED ERIC STANLEY MERRETT BM BCh, Colonial Medical
Service Acting Principal of the Medical School and Lecturer in
Physiology, Nigeria

PATRICK JOHN MONAGHAN MB, BS Chief Medical Officer
Western Samoa

Lieutenant Colonel WILLIAM THOMAS TAYLOR MB BCh, IMS
Deputy Director General, Indian Medical Service (Stores)

Honorary OBE (Civil Division)

KRIKOR SOLOMON KRIKORIAN Senior Medical Officer Palestine
Miss SOO KIM LAM LMS For public services in the Malayan
Union

MBE (Military Division)

Major JOHN COLSTON BABBAGE MB, ChB, RAMC

MBE (Civil Division)

KRISHNALAL VITHALAS AOALJA MB, BS For public and social
welfare services in Kenya

Captain NUGENT DAVY JEKYL MB, BChir, IMS Agency
Surgeon and Medical Officer, Central State Scouts North West
Frontier Province

Captain GERALD EDWARD McDONALD I.A.M.C.
ROBERT SCOTT REID MB, ChB Admiralty Surgeon and Agent
LAURESTON HEWLEY WHARTON, MRCS, LRCP Medical
Superintendent, Leprosy Hospital, British Guiana

VISIT TO CZECHOSLOVAKIA

Thirty British medical men were the guests of the Government
of Czechoslovakia from May 15 until June 1 and received an
enthusiastic welcome. The general impression gained was that
Czechoslovakian medicine was turning to the West, and in
particular to Great Britain, for help and inspiration in the
task of reconstruction. The Department for Diseases of the
Chest at the Bulovka Hospital, Praha, was visited. It is well
equipped and has a fine x-ray installation. The lines on which
treatment is carried out are similar to those at the best chest
centres in Britain. Both at the university clinics under Prof
Charvat and Prof Jurasek and also at the Bulovka Hospital it was
encouraging to see the high standard of medicine and surgery
and the enthusiasm of the young postgraduate medical per-
sonnel, a high proportion of whom spoke English. They still
need more English textbooks on medicine and surgery.

There is a shortage of nurses, mainly due to the higher wages
paid in industry. Their hospitals are also handicapped for
accommodation, with the result that beds are too close
together. Their practice of general anaesthesia is somewhat
out of date, but this is realized and they are making great
efforts to advance, as many postgraduate students as possible
are coming to Britain. The teaching staff is rather strained
at present training undergraduates to fill a national health
service.

Every spa is a first class health resort situated in beautiful
surroundings. The treatments are very little different from
those given before the country was cut off from Western
research hence they are still characterized by a certain
empiricism. Many of these health resorts are directly
supported by the Czechoslovakian Government and are
being used for the rehabilitation of workers of all classes.
All the patients seen appeared to be very content. Their diet
would certainly cause envy in similar institutions in Britain.
Tuberculous patients were getting as much meat in one day
as patients in England get in a week, and the meals were well
cooked and served.

ROYAL MEDICAL BENEVOLENT FUND

The annual general meeting of the Royal Medical Benevolent
Fund was held on June 5, when Sir Alfred Webb Johnson was
elected president, Dr C L Batteson, Honorary Treasurer,
and Mr V H Riddell, Honorary Secretary. A vote of thanks
was proposed from the chair, and unanimously carried, to the
British Medical Journal for the help extended to the Fund
during the past year, and especial thanks to it for the pub-
licity afforded to the Christmas Gift Fund and to Westmoreland
Lodge.

LADY TATA MEMORIAL TRUST

International Awards for Research in Blood Diseases

The trustees of the Lady Tata Memorial Fund announce that, on the recommendation of the scientific advisory committee in London, they have made the following awards for research in blood diseases, with special reference to leukaemia, in the academic year beginning Oct 1

Grants for research expenses and assistance—Dr Jorgen Bichel (Denmark), for work at Aarhus, Denmark, Dr Pierre Cazal (France), for work at Montpellier, Dr Pierre Dustun (Belgium), for work in Brussels, Dr Peter A Gorer (Great Britain), for work in London, Dr Maurice Guérin (France), for work in Paris, Dr Josef Japa (Poland), for work in Cracow, Dr Edith Paterson (Great Britain), for work in Manchester, Prof Edoardo Storti (Italy), for work at Pavia, Dr Johannes Clemmesen (Denmark), for work in Copenhagen Dr Tage Kemp (Denmark), for work in Copenhagen

Scholarships (for whole-time or part time research)—Dr Simon Iversen (Denmark), for work in Copenhagen, Dr Claus Frederik Munk Plum (Denmark), for work in Copenhagen, Dr Guido Hilmer Rafael Totterman (Finland), for work mainly in Helsinki

COLONIAL MEDICAL RESEARCH STUDENTSHIPS

On the recommendation of the Colonial Medical Research Committee, the Secretary of State for the Colonies has instituted ten research studentships for graduates in medicine and cognate sciences who desire by this means to prepare themselves for research work in tropical medicine and related subjects. The studentships will entitle the holders to an allowance at the rate of £260 per annum, free of income tax, and normally will be held for a period of two years subject to satisfactory report at the end of the first year's work from the supervisor, who will be nominated by the committee. They will be awarded on the advice of the committee and will be tenable at any approved university or other appropriate institution. If a student should cease his training before the expiry of the term for which his allowance was granted he will be required to refund any money paid to him for a period subsequent to the date on which he ceased his training. Any award will be terminable at any time in the absolute discretion of the Secretary of State. Candidates should be British subjects and graduates of British universities. Students successfully completing their courses will be offered posts in the projected Colonial Medical Research Service, details of which are not yet fully worked out, but they are intended to include superannuation provisions analogous to the federated superannuation system for universities and interchangeable with it. In view of possible employment overseas later, candidates for studentships may be required to undergo medical examination. Application should be made, through the head of the candidate's department, to the Secretary, Colonial Medical Research Committee, c/o Research Department, Colonial Office, London SW1 and should include, in addition to details of the candidate's academic record, some indication of the subject preferred.

At a meeting of the directors of the Society for Relief of Widows and Orphans of Medical Men, held on April 9, with Dr R A Young, president, in the chair, the deaths of one member and four widows in receipt of grants were reported. One widow had been on the funds for over 30 years and had received £2,300 in grants. A first application for relief was received from the widow of a member, and a yearly grant of £50 from the ordinary funds and £25 from the Bruckwell Fund were voted to her. Dr E J Blackett, secretary of the society for 42 years tendered his resignation, which was accepted. The annual general meeting will be held on Wednesday, May 21, at 5 p.m. Relief is granted only to the widows and orphans of deceased members. Membership is open to any registered medical man who, at the time of his election is residing within a twenty mile radius of Charing Cross. Full particulars may be obtained from the secretary, 11, Chandos Street, Cavendish Square, W 1.

Preparations and Appliances

DIATHERMY HAEMOSTATS

Mr WILSON HEY FRCS, Manchester Royal Infirmary, writes

For fifteen years almost all my patients at operation have been connected to some form of diathermy apparatus with the active terminal connected to haemostats of various types. The usual type is shown in the diagram and is in three sizes, $5\frac{1}{2}$ -, 7-, and 9-inch, the shortest for surface and the longest for deep work. The blades are fine-pointed because the bleeding vessels must be picked up lightly and finely so as to leave only a minute carbon mass. The central groove is for the insertion of a fine round-bodied needle which enables the instrument to be used for cutting, the smallest haemostat is not grooved. They are all of the Moynihan pattern with box joints and of stainless steel. To prevent the cable wire from

breaking at its junction with the connecting metal terminal both should be encased by a two-inch piece of rubber tubing. Attempts to cover the whole instrument except the points with some boilable insulating material have so far proved unsatisfactory. Consequently both the patient's body and the surgeon's hands must be insulated at all points liable to contact with the haemostat, which is clipped to a towel when not in use. The instrument will quickly discover punctures in the surgeon's glove although it can be held with impunity if grasped firmly by the naked hand. The importance of a close, even fitting of the inactive electrode, and of the protection of the patient from contact with all metal parts of the table should be known by every diathermy user. The current is controlled by the surgeon's foot.

Most named vessels and a few unnamed ones near the larger vessels should be ligated. The surgeon using only one haemostat throughout an operation naturally saves innumerable movements. He can in a few seconds seal a dozen or more vessels caught by his assistants. The saving of time, labour, and bleeding in many operations, such as the radical breast operation, is enormous. More perfect haemostasis is obtained in any wound, because the surgeon takes the trouble to stop every tiny oozing point which he could not, or would not, trouble to deal with by ligature. Bleeding in remote and hidden places can be more easily sealed. A radical breast amputation is done in a third less time, with less exertion, bleeding and shock, the average number of ligatures in the radical breast operation is twelve, in a subtotal thyroidectomy six. With an efficient assistant working his own diathermy only half a dozen haemostats are necessary for any operation.

In over 1,000 prostatectomies no single ligature has been used. One result is that the catgut bill for the theatre will diminish by more than 90%. Asepsis is more certain if vessel-sealing is caused by a minute fragment of sterile carbon than by a massive ligature, whether absorbable or unabsorbable. Very little practice is required.

These instruments are made for me by Messrs Chas F Thackray, Ltd, of Park Street, Leeds. They also make for me Stiles tissue forceps and Scott's long tonsillar forceps with similar connexions, but any type of haemostat can be modified for diathermy.

Correspondence

Calories

SIR—Prof J R Marrack's letter (June 7, p 821) is a welcome contrast to what was said in 'another place'. A further objection to the use of global statistics is that all the "calories" legally assigned to human stomachs do not reach them by a direct route. It is even said that some hardened criminals feed their chickens on potatoes. Whether this is a mere debating point or an appreciable source of error I do not know.

One might have hoped that 'calories,' like foreign affairs, would have been kept out of party politics, this has not been done—with potentially serious consequences. It may not be true that Government departments pigeon-hole scientific reports the contents of which are disagreeable to departmental chiefs but it *might* be true, and a contributor to your editorial columns quoted (April 19, p 535)—but without indication of source—some ominous sentences. Indeed, quite apart from political emotions most of us retain something of a child's pleasure in secrets. During the late war I sent in to an official committee a note on a small statistical matter. A few days later I extracted from a nest of sealed envelopes a numbered copy of my little note which I was instructed to peruse and return to headquarters by a similarly romantic route. For quite 30 seconds I was so thrilled that I could almost believe that the binomial theorem was my own invention, a deadly secret weapon I was aiming at the enemy's heart.

Dietary samplings on a sufficient scale to be valuable can only be undertaken by public authorities—central or local. It may still not be too late to revive the waning public faith in official statistics of "calories." In the first place an accurate and readable account of the way in which the official surveys are carried out should be prepared. I have little doubt that an accurate statement is already printed in some official document, but official accounts of statistical investigations tend to be either too curt or too technical for a general reader. The best plan would be to circulate a draft to the editors of the medical and other serious weekly journals. The final product should be well advertised. Then the monthly or quarterly statistics of 'calories' should be sent to all the newspapers whether they show improvement or deterioration. No doubt political half-wits on both sides would try to make capital out of rises or falls, but Ministers and Civil Servants always underrate the intelligence of the general public—naturally enough, because both are the prey of talkative fools and mistake a biased for a random sample of the public. If Government departments are too haughty and too secretive to do this, perhaps some of the more important local authorities could take on the work.

A statistical veteran is bound to have a (rather pathetic) faith in the efficacy and popular appeal of statistics, but almost anything would be better than the partisan handling of a subject of universal interest to which Prof Marrack has drawn attention. I need hardly say that the faults have not been only on one side. In fact if I had to pick out the worst and most reckless statements I—but this is to pass from statistics to politics, of which I am an even worse judge than of statistics—I am, etc.,

MAJOR GREENWOOD

Dried Egg and Salmonella

SIR—In the leading article 'The Egg as Poison' (April 5, p 456) reference is made to the isolation by Gordon and Buxton¹ of *Salm typhimurium* from ducks and *Salm thompson* from chickens. We would point out that in addition to these two salmonella types and to *Salm pullorum*, *Salm gallinarum* and *Salm enteritidis* the following have also been recorded²: *Salm californica*, *Salm bareilly*, *Salm monteideo*, *Salm anatum* and *Salm london*. Recently, we have also isolated *Salm bovis moribundans* from a serious outbreak of disease in chicks. There is little doubt that the presence of these latter types is associated with the importation into this country of American spray-dried egg which is known to have been fed to poultry either directly or indirectly in canteen or camp swill. The incidence of these salmonella types in poultry is very similar to that recorded³ in

man and pigs during the same period and an increase of over 200% in the incidence of avian salmonellosis was reported⁴ during the years 1941-4.

Unlike *Salm pullorum* these other salmonella types do not usually infect the ovary of the adult bird, and in a study of the pathogenesis of *Salm thompson* (in press) it has been shown that the infection of egg meat generally occurs only when conditions of egg storage are suitable to allow the penetration of the organism through the egg shell. It is probable, therefore, that the danger to public health from the consumption of clean chicken eggs is almost negligible.—We are, etc.

Treatment of the Maladjusted Child

SIR—I agree with the statement of Drs Elizabeth G W Barker and W Liddell Milligan in their article (June 7, p 805) that in the treatment of a maladjusted child removal from home is sometimes essential for a time. However, I cannot feel that admission to an adult mental hospital is the correct solution for this problem. If adequate hostels are provided by local authorities in connexion with their child guidance services, only a very few children cannot be given the accommodation they need. These few are those whose behaviour is too grossly disturbed for hostel or foster-home, and they are usually psychotic or pre-psychotic cases.

But according to the paragraph indicating the sources of the children admitted to St James's Hospital such cases only amount to 4% of their admissions. To admit other types of maladjusted children to an adult mental hospital seems to be just the state of affairs one wishes to avoid at all costs. If they could go to a special children's admission ward or villa it might not be so bad. But the article states "Some children were treated for a time in the male or female admission wards or villas, but the majority were housed in a special wing of the female convalescent villa." Reference is made to an annexe where children are transferred after a preliminary period of observation and, if necessary, treatment in the main hospital. This must mean the children mixing with various types of acute and chronic psychotic adults, which seems to be highly undesirable.

I would suggest that psychiatrists should stimulate local authorities to open more hostels for maladjusted children rather than open the doors of the adult mental hospital admission wards to children who, though maladjusted, do not show psychotic features. However, other mental health services would do well to follow the example of Portsmouth and make some special provision for the more seriously disturbed child who cannot be cared for in a hostel—I am, etc.,

Nottingham

W H WHILES

SIR—It is unfortunate that the work of seven years on 'Inpatient treatment of the Maladjusted Child' should have been reported by Drs Elizabeth G W Barker and W Liddell Milligan (June 7, p 805) in terms so vague that its evaluation is impossible. Ages, we are told, "varied between 4 and 15 years," but the majority admitted were between 7 and 11 years old, with a peak at 9 years, etc. This tells us almost nothing about the scatter. In this context, "the majority" might be anything from 51% to 98%. Period in hospital is similarly treated. The paragraph on intelligence adds little but inaccuracy to the general vagueness. The average intelligence was not unnaturally above the normal after the lower end of the distribution curve had been gratuitously eliminated. No mention is made of the test used. From the girl of 13 with an IQ of 170 I think one can safely infer that the test used was Cattell Scale III. It would have been less misleading if this fact had been mentioned, since IQs on this test particularly at the upper end of the scale are not comparable with other tests. Though Cattell's scale does go up to 20 years further than most psychologists would allow there is certainly no justification for speaking of a mental age of over 20.

There was a positive correlation between stealing with enuresis and rejection. Coefficient of mean square contingency presumably? But, since the sample was by no means large, the standard error of C could not be calculated. A 2x2 contingency table would therefore seem to have been indicated, which does not give a correlation coefficient. In any event, what about the associations stealing rejection, stealing-enuresis, and enuresis rejection separately? From the foregoing account it will be seen that some 80% of the children were greatly benefited by in-patient treatment. This can only be seen from the statement that roughly 80% returned home. Without some more valid criterion of benefit no conclusion can be drawn.

It is quite possible that much valuable therapeutic work has been done which would warrant a vast extension of in-patient treatment of maladjusted children, but in the report of the work there is not one shred of evidence to support this conclusion—I am, etc.,

Health of Children Attending Day Nurseries

SIR—Truly the fat is in the fire! Dr Margaret E McLaughlin's observations (May 3, p 591, and May 10, p 631) suggest—as some of us had already begun to suspect—that in erecting and staffing day nurseries this country has gone to a great deal of trouble and expense in order to make a great number of children less healthy. What a douche of cold water for our sentimental and well meaning "social workers"! What a further shock for that once smugly self-satisfied institution at the bottom of Whitehall! No wonder there is a protest that one investigation is not enough, that further observations must be made (with the obvious hope that the later will refute the earlier). By all means let us obtain more facts, indeed we must have the fullest investigation into the whole problem. The health of the children is a matter that concerns the whole country.

There is one aspect of the question which has hardly been considered at all—many of those who advocate day nurseries are aware of their disadvantages but believe in their necessity. Dr Nora Johns, for example, refers to "mothers forced to work." Now who are these mothers who are "forced" to work in time of peace? There are a relatively small number who have lost their husbands, but in my experience of twenty-seven years of general practice the great majority of these women are (a) masculine, (b) irresponsible. A masculine woman is not typically an Eton cropped female with a masculine figure and hair on her face (this is an extreme example), but she has certain well defined characteristics—menstruation begins late and is painful, she marries late and suffers from dyspareunia or frigidity, in pregnancy vomiting is troublesome, labour is difficult, and she does not breast-feed her baby, she has one or at most two children. On the other hand she does well at business, gets on well with the men—as a man would—and earns a good salary. She dislikes housework but likes going out to business. In short she does well at men's jobs, badly at women's. Now this type of woman frequently marries a man who from ill-health or laziness or both does not earn a good wage, hence she is "forced" to go out to work (which in fact is exactly what she wants to do).

She is also irresponsible for having brought a child into the world, she escapes the responsibility for a large part of its early upbringing, and incidentally passes it on to the care of other women who have no children of their own but take a hand in bringing up other peoples'. So if anything goes wrong the mother blames the nursery and the nursery blames the mother.

Are we Sir being fair to the children?—I am, etc.,

London SW 15

F GRAY

Penicillin for Osteomyelitis in Childhood

SIR—Reading the paper by Messrs T Twistington Higgins and Denis Browne and Dr Martin Bodian (May 31, p 757) on the treatment of acute osteomyelitis with penicillin based on three cases from Great Ormond Street Hospital we have got the impression that the administration of small doses of penicillin (1 000 units per lb (454 g) per 24 hours) the aspiration of pus without further surgery, and early mobilization form the method of treatment which the authors recommend for all cases of acute osteomyelitis in childhood irrespective of gravity or

age. As we think that others may also have got this impression we should like to advance a word of caution for the benefit of those without much experience in the use of penicillin in this disease.

We have ourselves only treated cases from an older age group than those on which the experience of Higgins *et al* is based, and our remarks must therefore be understood as referring primarily to these. Fifty-four out of our 55 cases have been over two years of age (five were adults), whereas 16 out of the Great Ormond Street series of 31 cases were under two years. Green and Shannon pointed out from a series of 95 cases under two years, in 1936, the difference in the pathology and the reduced severity of the disease in infants, and to this difference may probably be attributed some of the discrepancies between our experience and theirs. Further, the cases from Great Ormond Street appear to have been less severe than ours, 50% of our cases and only 7% of theirs had positive blood cultures and it is especially the severely ill cases which we find do not respond to the treatment recommended. We differ on three main points—type of surgery, dosage of penicillin, and immobilization.

Type of Surgery.—In our hands aspiration has proved an unsatisfactory method of removing pus, and we have studied the table attached to the paper with great care for an explanation of the discrepancies between their experience and ours, but we confess that the more we study the table the less we understand the text. These authors write "Where our treatment differed from that generally followed was in 13 cases in which pus formed outside the infected bone," and that "surgery was confined to aspiration of pus." But when we read the table we find that 17 cases had some form of surgical treatment and that of these five had open surgery. "Abscess incised" occurs three times, "bone drilled" once, and "sequestrectomy" once. The drilled case had apparently already had nine aspirations. Thus only twelve of the 17 cases needing surgery were treated with aspiration alone, but, of these, four had a septic arthritis when treatment was started, and the data given suggest rather a primary suppurative arthritis complicated by osteomyelitis—none had a *Staph aureus* infection—and we fail to see why they were not grouped with others of primary suppurative arthritis which are dealt with separately in the paper. Two further cases with one aspiration only had negative local cultures, and presumably no pus was obtained.

Thus we are left with only six cases of acute osteomyelitis with pus formation treated by aspiration alone. None of these cases had a positive blood culture and they were therefore probably of the mild type. One case had acute osteomyelitis of the maxilla, his result was good, but so it was in the two maxillary cases treated by open surgery. Two cases had osteomyelitis of the fibula and now have normal radiographs, three tibias complete the story, but they have had considerable bone damage—one after 11 aspirations—and if one includes the tibia which had nine aspirations and then drilling of the bone the efficiency of aspiration for the removal of pus is hardly convincing in this series. If the cases with joint involvement must be included, the picture is even less gratifying. One shows delay of epiphyseal development, another ankylosis, and another no evidence of ossification in the heads of the femur and humerus. These cases may now have normal function, but with abnormal epiphyses their future is by no means bright.

In our experience we cannot satisfactorily remove pus by aspiration, and have repeatedly proved this by aspirating on the operating table immediately before incision as much pus as we could from the soft tissues. Invariably we have found on incision considerable quantities of pus left in the soft tissues, sometimes two or three times the amount aspirated, apart from the pus within the bone, which is of course never tapped by aspiration. There may be some fault in our technique, but when we read that six, seven, nine, eleven aspirations have been performed by these authors, we are tempted to think that it is not our technique but the inherent limitations of aspiration which are to blame. We know that in the presence of appropriate blood levels of penicillin, and after adequate removal of pus and of any dead tissue by open surgery and drilling of the bone to reduce the danger of its necrosis by pressure, new pus does not form, and for this reason we have advocated primary suture in all cases thus overcoming the reasonable objection offered by these writers to incision—that of secondary infection of an "open wound." If full sterile precautions, as used for clean bone operations, are observed at operation and the part is afterwards adequately immobilized, secondary infection does not occur.

Penicillin dosage.—Again we repeat that we have almost no experience in infants, but in older patients we have been forced to adopt a bigger dose for two reasons—first, because one must allow for organisms of greater resistance than the standard Oxford staphylococcus, until the laboratory report on sensitivity is obtained, and secondly because the bigger dose causes a more rapid control of the septicaemia and consequently of the toxæmia, whose continuation

or even fatal results in severe cases of the disease. It is of mention that the blood culture remains positive from our to seven days which we regard as far too long. We have not ourselves tested many cases for repeated positive blood cultures, because of the rapid improvement in their clinical condition, but in those cases which we have tested the second culture has been sterile except in one case which had a penicillin resistant infection for which we had at the time insufficient penicillin. We advocate an arbitrary daily dose of 400,000 units (equal to the whole course advocated by Higgins *et al* for many of their cases) falling to a minimum of 200,000 units daily given by intramuscular drip for patients of all ages. If infants are unsuitable for drip administration we should give this dose by two hourly injections during the acute stage in order to be certain of a constant bacteriostatic level of penicillin in the blood.

Buchanan in a paper on dosage of penicillin in infants, for infections generally advocates a routine dosage of four times that used by Higgins *et al* given three- and not four hourly (4,000 units per lb per 24 hours by three hourly injections). She found that 1,000 units per lb per 24 hours was often insufficient for obtaining inhibition with serum dilution 1/1, that 2,000 units per lb was sufficient, but that 4,000 units per lb gave better maintained results. We read in the paper by Higgins *et al* that one child with a streptococcal infection of 12 times the normal resistance to penicillin made a complete recovery on the standard dosage of penicillin and that makes us wonder how much has penicillin really affected this series. But on referring to the table we see that 'complete recovery' includes 'erosion of the head of the humerus, now delay in epiphyseal development'. And it may be that some of the local recoveries do not differ as they should from those which would have been seen in pre-penicillin days.

Immobilization—We read in the paper that 'immobilization was not prolonged much beyond the period of penicillin treatment, and movement was encouraged as soon as it was painless even in cases with marked radiological changes' (The italics are ours). We should have been afraid that such a policy might have produced sooner or later a pathological fracture, a fact which is substantiated by these authors' experience for in the table—again without comment in the text—we find 'fracture' in a case of osteomyelitis of the tibia. Before allowing movement and weight-bearing we do carefully consider both the clinical and laboratory findings for evidence of residual inflammation on the one hand and the radiograph for soundness of the bone on the other, and we tend to conservatism if there is any doubt. Only such careful consideration can prevent unnecessary complications such as pathological fracture.

We are very sorry to be forced to stress our points of disagreement with the views of Higgins *et al*, especially as they offer us one of the largest series of acute osteomyelitis in infants treated with penicillin which has so far been published, and the authors' conclusion on cases in this group can be discussed by few with comparable experience.—We are, etc

Oxford

J. TRUETA
M. AGERHOLM

SIR—We have read with great interest the report by Mr T. Twistington Higgins, Mr Denis Browne, and Dr Martin Bodian (May 31, p. 757) on the treatment of osteomyelitis with penicillin. Our own experience in one surgical unit at the Royal Hospital for Sick Children Glasgow confirms many of their findings and our preliminary report is awaiting publication. We find comparison with other reports difficult as the virulence of the disease varies in different localities and there are no fixed criteria of diagnosis nor standards of cure. It would seem desirable for example to classify separately infants under 1 year old. In this age group the clinical picture is not strictly comparable with acute staphylococcal osteitis in older children.

The report on blood cultures is confusing. It would appear that only two positive staphylococcal cultures were found. In our own series positive cultures of coagulase positive staphylococci were found in 20 of the last 36 cases of acute osteitis. During this period we treated 18 cases of subacute staphylococcal osteitis. Infections of the skull facial and small bones tend particularly to be subacute in type. We find it difficult to concur in the view that the abortive action of penicillin is so great that a diagnosis made on purely clinical grounds may never be confirmed in any other way. Staphylococcal soft tissue abscesses are common in children and in the absence of radiological evidence of bone involvement we prefer to exclude unconfirmed cases from our series even in the presence of a positive blood culture.

As regards dosage we have been unable to maintain a therapeutic blood level of penicillin using 1,000 units per lb (0.45 kg)

body weight, nor have we been able to maintain an adequate level for 4 hours with individual doses of less than 20,000 units, irrespective of age and body weight. Routine marrow punctures are performed in all our cases, and penicillin sensitive staphylococci have on occasion been grown from the marrow until the 35th day of parenteral administration. Surely penicillin must be given until the marrow cavity is sterile? It is difficult to see how this can be achieved by parenteral administration in the case in which the blood supply to the affected area of bone has been cut off. We agree wholeheartedly about the dangers of secondary infection but consider that there is still a place for evacuation of pus by incision followed by primary suture.—We are, etc

Primary Malaria in London Children

SIR—Many readers will have been interested in the report by Drs C. Bland Levick and M. E. MacGregor (May 31, p. 764) on primary malaria in London children. In view of the fact that inoculation malaria produced either by means of a blood transfusion from a donor with latent malaria or of an injection by a dirty hypodermic syringe, is the commonest form of primary malaria in a person living in a town in a non-malarious country, it is surprising that no definite statements excluding these possibilities were made. In neither case do the histories suggest that this was a possible explanation, and as there was more than one relapse in the first case it seems most unlikely that this was a case of trophozoite-induced malaria, yet negative statements would have added to the scientific value of the paper. Perhaps these could now be made—I am, etc,

London W 1

L. EVERARD NAPIER

Oxygen Poisoning in Man

SIR—Dr Kenneth W. Donald's article on oxygen poisoning (May 17, p. 667, and May 24, p. 712) is remarkable for the record number of human experiments done on volunteers and the proof that no ill results from convulsions produced by oxygen poisoning. He does not however, make clear that the research was carried out in the experimental department and with plant and appliances (only three units of which are figured in the articles) which Sir Robert Davis had the prescience and enterprise to set up at great cost at Messrs Siebe, Gorman and Co's works during the many years of research carried out by him under deep diving, high altitude, and poison gas conditions, in which I have assisted, and lent by him for the use of the Admiralty voluntarily and free of charge for the duration of the recent war. Dr Donald thanks Sir Robert for help and advice while grateful acknowledgment is given to others. It should have been recorded that the whole research was made possible by the loan of Sir Robert's experimental department and the information on past experiments and facilities afforded him at Messrs Siebe, Gorman and Co's works, including offices, sick bay, etc.

Dr Donald is entirely wrong in attributing to the late Prof J. S. Haldane work done in conjunction with the Admiralty Deep Diving Committee of 1930-3 of which I was the physiological member. Sir Robert Davis, at his expense and with the help of Capt. Damant, by extensive researches on animals extended the diving decompression tables set up by J. S. Haldane for depths up to 210 feet (64 m). The experiments showed that while the Haldane tables were satisfactory up to 210 feet, they were not satisfactory beyond the depth, and new factors had to be taken into account to make the tables of decompression safe for 300 feet (91.4 m) and over reached at the trials in Loch Fyne. To prevent any excess of CO in the breathing circuit Siebe Gorman and Co contrived the addition of an injector apparatus (and CO absorbent chamber). This invention and the new tables proved most satisfactory, and the latter were adopted by the Admiralty and have been used successfully ever since.

The danger of breathing pure oxygen at depths beyond a certain pressure have been known to, and avoided by, Sir Robert Davis for many years. In 1929 he submitted to the Admiralty for trial a self contained diving apparatus in which a mixture of 50% oxygen and 50% air was used at depths to about 70 ft (21 m). Trials by H.M.S. *Caro* in the Mediterranean proved this apparatus to be 'highly efficient and satisfactory,' but owing to a financial

renchment policy at that time its use was not extended to smaller vessels as proposed. It was, however, supplied and used by foreign countries with quite satisfactory results and at greater depths when using suitable mixtures of oxygen and air. Apparatus on the same principle was used extensively in the last war for midget submarines, human torpedoes, shallow water diving apparatus for removing mines, suits with frog feet (a very old invention), etc. The midget submarine successfully used against the *Tirpitz* was built with an emergence chamber, as designed and patented by Sir Robert Davis early in 1915, the diver using it being equipped with self contained diving apparatus enabling him to leave the vessel, place an explosive charge, and to return thereto. At the time, however, it was thought that such small vessels could not be usefully employed.

In the submersible decompression chamber invented by Sir Robert oxygen is breathed by the diver during decompression from 60 ft (18.3 m) to the surface to shorten the decompression time. No oxygen poisoning symptoms have resulted during the many times of its use. Dr Donald's results show that shallower depths are not always safe. The mixture of oxygen and air should, therefore, always be used as recommended by Sir Robert Davis.

The greater risk of oxygen poisoning found by Dr Donald in under water experiments cannot, he says, be attributed to CO_2 accumulation, which, as shown by me, enhances oxygen poisoning. He found no excess of CO_2 in the breathing chamber, but has left out of account the dead space of the mouthpiece and respiratory air tubes. An experienced diver told me he believed the effect was due to rapid shallow breathing by less experienced and stable men when under water. Such breathing would greatly enhance the effect of the CO_2 in the dead space.

Argyll Campbell showed that oxygen breathing interferes with the transport of CO_2 from the tissues and puts up its tissue partial pressure greatly. Similarly Bean, J. W. (*Physiol. Rev.* 1945, 25), has pointed out that nitrogen, and still more the heavier gas argon, at high pressures interferes with the diffusion outwards of CO_2 from the lungs. Helium and hydrogen, owing to their light weight, have in comparison no such effect, and have no narcotic effect when used with oxygen for deep diving. CO_2 may then be the cause both of oxygen poisoning symptoms and the anaesthetic effect of nitrogen in deep dives. This last question can be settled by measuring the partial pressure of CO_2 in the tissues when breathing argon and oxygen. The heavier gases krypton and xenon have much greater effect but are very difficult to obtain (Lawrence, J. H. *et al.* *J. Physiol.* 1946, 105, 197). So soon as enough argon can be obtained a trial will be made.

I may add that a copy of Dr Donald's report to the Admiralty was shown to me a year or two ago and I then pointed out the claims of Sir Robert Davis for adequate recognition, but no notice of these has been taken.—I am, etc.,

Chalfont St Peter Bucks

LEONARD HILL

Refrigeration Anaesthesia

SIR—In his interesting article on the results of refrigeration analgesia in Melbourne Mr E. S. R. Hughes (May 31, p. 761) seems to have reached much the same conclusions as British anaesthetists. At the same time there is one point which should I think be clarified. Mr Hughes does not regard a tourniquet or its equivalent as of much importance—for example, "the tourniquet is not an essential requirement at any stage of the procedure and may be dispensed with altogether." With all deference may I suggest that the proper application of a tourniquet is an essential and indeed a vital part of the technique?

If a limb of an aged and toxic patient is cooled down to 5°C without a tourniquet the process takes a long time and is accompanied by a pronounced fall in the general body temperature. This is a most dangerous condition and is frequently followed by gradual deterioration and eventual heart failure, often associated with anuria and a low grade bronchopneumonia. It will be noticed that in Mr Hughes's series of 25 amputations under refrigeration the total mortality rate was 44%, while 20% of cases developed a fatal bronchopneumonia. These figures seem high and it would be interesting to know how many of the fatal cases were refrigerated without a tourniquet. The latter device can be applied painlessly if a sausage shaped ice bag is applied at the appropriate level round the limb for 30 minutes beforehand. The time for subsequent refrigeration can then be reduced to $1\frac{1}{2}$ to 2 hours. In our experience it is better to avoid post operative refrigeration of the stump in spite of some theoretical advantages.

It may be argued by those who dislike tourniquets that therapeutic limb cooling is often carried out without them in cases of defective circulation in order to lower the tissue

metabolic rate to a point at which the limited blood flow is adequate. This is true, but the necessary temperature drop is not great, and such patients are usually younger and fitter than those undergoing amputation for gangrene—I am, etc.,

St Albans

C. LANGTON HEWER

Basal-cell Carcinoma at Site of Trauma

SIR,—Trauma rarely figures in the aetiology of basal-cell carcinoma. The following case is similar to that recently recorded by Reah (1947).

CASE REPORT

Male, aged 38, brunet, normal skin texture. In 1943, recaptured after some months at liberty in Germany after escape from prison camp, he was beaten about the head and face with a revolver butt. Lacerations were produced on the forehead, cheek, and nose, and were sutured shortly afterwards, stitches being removed after about a week. All the wounds healed normally except for one gash on the forehead over the outer end of the left eyebrow.

This lesion never healed completely, and it discharged a little pus until early in 1947, when it dried up. There had been a very slow peripheral spread during the whole time. When first seen in March, 1947, the lesion was a typical superficial cicatrizing basal cell carcinoma, $3/4$ in by $1/2$ in (1.9 cm by 1.25 cm), with central scarring and elevated pearly edge. The diagnosis was confirmed by biopsy.

—I am, etc.,

Pethidine in Labour

SIR—I would like to comment on that masterly paper by Miss Josephine Barnes (April 5, p. 437) on the use of pethidine in labour. I must say that I have not been so favourably impressed by the results following the use of this drug. I agree with your correspondent, Dr James Ross (May 24, p. 738) when he says that "its action is unreliable." That has been my own experience.

I cannot agree with Miss Barnes that pethidine satisfies the first part of her No. 1 criterion. In my experience—a much smaller one than that of Miss Barnes—an alarming, sudden, and anxious drop in blood pressure has immediately followed the administration of the drug in several cases. As regards the effect of pethidine on the baby, I have almost always found the infant slow to breathe and giving definite cause for worry, even in cases where such could not be attributed to operative interference or abnormality of any kind. Like Dr Ross I believe heroin (diamorphine hydrochloride) to be a vastly safer and more reliable drug, and I have discarded pethidine altogether.—I am, etc.,

Belfast

J. H. P. GIFF

Behcet's Syndrome

SIR—Dr E. W. Prosser Thomas's article on Behcet's syndrome (Jan. 4, p. 14) has just come to my notice, and I think it will be of interest to express our views on the so called syndrome as well as on thrombophlebitis. In the *Proceedings of the Medical Society of Athens* (1930, p. 586) Dr B. Adamantiades presented the first known case of recurrent iritis with hypopyon, insisting at the same time on the small ulcerations of the mouth and genitalia. All these three elements were characterized by recurrences, appearing either at the same time or at independent periods. Later (*Annales d'Oculistique* 1931, 168, 271) followed the same description of this syndrome in French. In 1931 Dr Daskalopoulos (*Proceedings of the Greek Medical Society, Athens*, p. 717) describes a record case. There follows the description of Whitwell (1934), and later again in 1937 Behcet, of Constantinople, describes the syndrome in the *Dermatologische Wochenschrift* (105, 1152), in German. The same author (Dr Adamantiades) in a careful study of two other cases which came under his notice, found that a fourth element is quite common and describes in detail the thrombophlebitis either of the central vein of the retina or of the legs (Greek Ophthalmic Society, June 7, 1945, and *Annales d'Oculistique* 1946, 179, 143). This element was also observed by Urbanek, J. (*Zt f. Augenh.* 1929, 69, 174),

Vol. 1 (Zt f Augenh 1937 91 129) Delord E (*Annales d'Oculistique* 1941 177 366) and Tebevan and Kalfayan (*Archives d'Oculistique* 1945 178 335), either on the legs or in the retina. We are pleased to see that this thrombophlebitis was also observed by Dr Prosser Thomas.

Dr Adamantides describes this syndrome as the complex syndrome of recurrent iritis with hypopyon which according to the rules of nomenclature is the name and term accepted by Greek medical literature. May we add that this syndrome is compared to the disease known as 'periodic ophthalmia (moon-blindness) of horses' according to the same author. I should like to add that Dr Thomass contribution to the subject is much welcomed in Greek medical circles in Athens—I am, etc

Athens

NIKOS LORANDOS

Vaginal Operations

SIR—May I be allowed to reply to Dr T F Redman's letter (May 31, p 784), in which he criticizes my statement 'carcinoma of the vaginal portion of the cervix only occurs in women who have been pregnant'. Perhaps I did not make myself clear enough in that in this statement, I referred only to that type of carcinoma which arises from epithelium similar to that which lines the vagina—namely, squamous-celled carcinoma. I quite agree that columnar-celled carcinoma occurs quite frequently in the cervical canal in nulliparous women. This type of carcinoma, although occurring in the vaginal portion of the cervix if this be judged on a strict anatomical basis should, I think, be considered on a pathological basis—namely as a continuation of the uterine cavity, although of course the type of columnar-celled carcinoma is modified in the endocervical portion of the uterus.

I have investigated the 108 Mayo Clinic cases of stump carcinomata referred to by Dr Redman and a considerable proportion of these would seem to be cases of columnar-celled carcinoma, and the incidence of these cases would not be affected by previous pregnancy. Again, in this series I cannot find any reference to the question of a previous abortion. This point I consider important since I should like to make it clear that when I mentioned pregnancy I also included those cases with a previous history of abortion. The table of Dr Hurdon in which she compares the incidence of carcinoma in single and in married women is of little value, since pregnancy and abortion are not confined entirely to married women.

My original statement was based upon the teaching of Mr T G Stevens and in my five years as his registrar I had ample opportunity to confirm the aetiological relationship which occurs between the incidence of squamous-celled carcinoma of the cervix and pregnancy or abortion. Naturally I am aware that this type of investigation must of necessity be unsatisfactory since one has to rely entirely upon the truthfulness of one's patient. If however, Dr Redman is prepared to concede that squamous-celled carcinoma of the cervix occurs more frequently in women who have been pregnant than in those who have not been pregnant then my original object which was to strongly support Mr Wilfred Shaw in his advocacy of vaginal hysterectomy in certain types of prolapse will have been attained—I am etc

JOHN H HANNAN

Printed Clinical Lectures

SIR—I read with considerable interest Prof L J Witts's review (May 3 p 602) and Dr Edwin Bramwell's letter (May 24 p 741) on this subject and would like to support Dr Bramwell. I feel there is a distinct place in academic medicine for the clinical lecture from the verbal and written point of view. A lecture centred round a patient is invested with a definite personal touch and the subsequent committing of it to print may be of benefit to those who were unable to be present. I have derived much pleasure and profit in reading over my notebook of notes taken while a clinical student. These represent a very fascinating medical and surgical anthology in diverse topics of fundamental clinical importance.

Doctors feel that to day there is a certain deterioration in the art of lecturing and it should be the rule that only those members of an academic staff of a hospital should lecture who

are gifted in that manner. A man may be a born clinician but not necessarily a teacher as well. It is inspiring to pick up a volume of clinical lectures by such a giant as Sir James Paget who we are told would rehearse his lectures walking up and down in the open air to realize the profundity of clinical as well as classical knowledge that he possessed. An apt literary quotation may do much to tone up a discourse on a dull topic although, well taught, medicine never should be dull. As a student at Bart's I recall many an issue of the hospital journal contained a printed clinical lecture delivered by one of the chiefs of the hospital. I was always grateful to the editor for printing it and so making it available to a far wider audience—I am, etc.

J B GURNEY SMITH

General Knowledge and General Practice

SIR—The subject of medical education is one of perpetual joy for committees and correspondents. Representatives of all branches of medical science—the pediatricians, the physiologists, the psychiatrists, the protagonists of social medicine and the others—continually advocate extending the curriculum (with especial regard to their own subject) so as to make the student a more capable medical practitioner. Neither they nor anyone else seem to consider making the student a better citizen, humanist, or scientist. While they stress the technique of the profession they forget the broad cultural background.

This letter is a plea for recognition that a 'duly qualified medical practitioner' able to treat disease is not necessarily a 'doctor' fully competent to take an active part in public life and enlightened circles. For that he needs a fair amount of extra-curricular non medical knowledge. He must know not only the divisions of the peroneal artery but also the divisions of the Liberal Party, not only the development of the normoblast but also the development of uranium 235, not only the difference between Arnold Pick's disease and Friedel Pick's disease but also the difference between George Moore and Henry Moore.

Since matriculation many of us have had no formal contact with politics and the humanities, economics, and the arts, and only the most far sighted of our teachers bothered to remind us of their existence. The London medical schools (in particular) seem nowadays almost to be technical colleges for the study of anatomy, cardiology, and all the other 'subjects'. Perhaps it is still possible for an enlightened dean to sponsor a series of lectures on the economics of foreign policy or a courageous university to introduce into the third MB a question on existentialism. It is the examining bodies who, by not insisting on a reasonable standard of general knowledge, allow some number of medical practitioners to be merely

'clinical technicians'. To raise this standard it is up to these bodies to include a compulsory general paper in the final examination. The practice in many countries abroad (with what results I do not know) of having medical students take an arts degree first is I believe considered impractical here for reasons of time, expense, and shortage of doctors—I am, etc

London NW 4

D N BARON

Remuneration in NHS

SIR—It may take many months for a doctor's capitation list of new Health Service insured persons to approximate in numbers to his present adult private patients. There will therefore be a considerable time lag during which every general practitioner entering the new Service will find his income depleted yet he will be working harder than ever with so many potential patients awaiting his 'free' services—patients who do not appear on his list and for whom he will receive no payment until they do so appear—usually when they are in need of treatment which may be months or even years after the appointed day.

I write to point out that steps should be taken now to ensure that future insurable persons will in fact apply for inclusion on the list of the doctor of their own choice on the given day, not only by arranging for publicity in the daily Press but by the distribution of application forms to post offices, insurance agencies and doctors and that some penalty might be devised for those who do not join within three months—for instance,

that for every month delayed beyond three months a patient should pay private fees for one month before qualifying for free treatment

The establishing of a central pool into which bulk payment is made by the Ministry for all persons insured and from which payments would be made to doctors according to the numbers on their lists is not good enough, as practices now mainly private ones would inevitably suffer at the expense of those with full or preponderating panel lists—I am, etc.,

Birmingham

W W NEWTON

Shortage of Nurses

SIR—I am grateful to "Surgeon Commander, R N" (May 24 p 740) for so ably expressing the official opinion on the training of medical orderlies. I suggest that this attitude has done and is doing a great deal of harm to the prospects of ex-orderlies. The Service authorities consider that a Service-trained medical orderly should receive full civilian recognition. The General Nursing Council, not unnaturally, is unwilling to grant such recognition until Service nursing examinations are made to conform to certain standards. Neither party will budge, and the result is a deplorable impasse with the unfortunate orderly as the main sufferer.

Those in the Services who are interested in the welfare of orderlies would gain more by co-operation than by this obstinate "good enough for Nelson" attitude. I entirely agree that many ex-orderlies are experienced nurses suitable for immediate inclusion in the Register. My only concern is that future orderlies should receive a training—and a diploma—that will place their status beyond question—I am, etc.,

London NW 1

R HOWELL ROBERTS

SIR—With reference to the letter of 'Surgeon Commander, R N' (May 24, p 740) on shortage of nurses, I feel he is an old friend of State Registered nurses and therefore deserves an answer from one of them. I have met him occasionally during my 64 years in the Q A R N N S R. He walks into a ward, gives his orders to the first V A D or orderly he meets, and when to his pained astonishment these orders are not carried out, who does he blame? Not the V A D, not the orderly, no, the sister in charge, who did not receive the order, is held responsible. The Commander has forgotten that she has probably spent 5 years in training and so is the obvious person to receive his orders and see that they are carried out. He may not know that from 1939 onwards all V A Ds were urged to leave their organization and train as S R Ns—an opportunity which was availed of by many, in fact all who were genuinely interested in nursing.

Surely "Surgeon Commander, R N" would be among the first to condemn a quack in his own profession. I do not hesitate to condemn them in mine. As a wartime measure the services of V A Ds were much appreciated, but to suggest that they should be granted State Registration on demobilization (even with recommendations by Service medical authorities) is to revert to the days of the Crimea. But perhaps this is pleasing to the Commander whose ideas are purely retrogressive, he would then have the opportunity of becoming a second Florence Nightingale.

The following facts may be of interest. (1) All sisters that I met in the Navy were agreed that they were unable to allow even the simplest dressing to be done by V A Ds, whose technique, unless under close supervision was 'fingers instead of forceps'. If the Commander is willing to sacrifice asepsis for speed in his zeal to dismount the GNC from its "high horse" then may it not be my lot to fall into his hands or into those of his staff? (2) My sister, an M O in the R A M C, while convalescing from typhoid fever, assisted the sister of her ward by charting the temperatures from the 4-hourly book. Her own temperature was carefully recorded each night by the night V A D as anything varying from 98.4 F (36.9°C) to 100.8 F (38.2°C) despite the fact that neither the V A D nor the thermometer had made any appearance during the night. To such people does 'Surgeon Commander, R N' entrust the care of the sick. He must remember that "a little learning is a dangerous thing"—I am, etc.

Glasgow Co. Cork

EX Q A R N N S R

SIR—The full effect of the "Mowbray" scales for male and female domestic workers became known after the memorandum (June 7, p 819) on this subject was written. The financial position of nurses in relation to that of resident ward maids and ward orderlies in London hospitals is now seen to be even more anomalous than was stated in the memorandum. It appears that a nurse who becomes State registered in general or fever nursing and remains in hospital as a staff nurse without securing a position as ward sister must now work for twelve years before she attains to the remuneration of a ward maid and for twenty years before her remuneration, then at its maximum, becomes equal to that of a ward orderly. This statement takes account of the average additional earnings of a ward maid and orderly for Sunday duty and the higher maintenance allowance paid to them during absence on sick or annual leave. During all these years the nurse has to put up with the inconvenience of regular turns of night duty without extra pay, and in some hospitals at present has to work longer hours than the maids and orderlies—I am, etc.,

London SE 13

H STANLEY BANKS

Calculation of the Colour Index

SIR—The publication by Dr R Elsdon-Dew of yet another way of calculating the colour index (May 24, p 723) would seem to justify one more plea for discarding a conception which has outlived its usefulness.

For the estimation of the colour index the haemoglobin value is usually given in per cent instead of in its absolute figure as is usual for every other blood constituent. The former way is particularly undesirable, as the values refer to a single standard of alleged normality (100%) irrespective of normal variations in haemoglobin content and of differences between age groups and sexes. Continuing the use of the colour index would also mean perpetuating the misconception of "hyperchromic" anaemias. Although it has been recognized long ago that an increased colour index is invariably a function of an increased cell volume (e.g., Naegeli, O., *Blutkrankheiten und Blutdiagnostik*, Berlin, 1931, p 108), such an index is commonly misinterpreted to mean a pathologically high haemoglobin concentration. Such fallacies will soon die out when blood findings are reported in terms of red blood corpuscles (per c mm) haemoglobin (g/100 ml), mean corpuscular volume (cv) and mean corpuscular haemoglobin concentration (%), a nomogram for finding the latter values and that for mean corpuscular haemoglobin (γ) is given in M W Wintrobe's *Clinical Hematology*, Philadelphia, 1946, where also the subject of this letter is discussed at length.

As a matter of archaeological rather than practical interest, the Norwegian physician S Laache, who introduced the conception of the colour index (*Die Anämie*, Christiania, 1883, p 110), later believed it to depend on differences in degree rather than in quality of anaemic conditions (letter to M Regnault, quoted in the latter's *Anémie Pernicieuse et Cancer Latent de l'Estomac*, These de Lyon, 1904/5, No 117)—an unusual case of an author denying for a wrong reason the value of his own discovery—I am, etc.,

London E 2

HERBERT LEVY

Another Name

SIR—I am no psychiatrist and cannot therefore venture an opinion on the necessity for the latest proposed addition to the medical dictionary, but as one who still prides himself on the preservation of a smattering of the classics may I deplore Dr D Cappon's choice (May 31, p 784) of a possible term? I fail to see any parallel between "anosognosia"—a legitimately derived Greek word meaning "no disease-appreciation"—and "abmengnosia" a most illegitimate Graeco Roman hybrid which seems to mean, if anything, "away from the cultivated-mind-knowledge"—a possible symptom of existentialism.

This Shakespearian attitude to the classics does more credit to Dr Cappon's intentions than to his achievement. Averse as I am from the multiplication of nomenclature, I hesitate to coin a new term myself and would prefer anyway to await the efforts of more experienced classical scholars. Perhaps Dr J N Fell would oblige—I am, etc.,

London SW 6

M C T REILLY

POINTS FROM LETTERS

Returning Fee

Dr EGAN R BROOKS (near Stockport) writes: I deplore the decision made by Dr P B Corbett (May 24, p 741) that a returning fee should be paid for each day over the booked date of a confinement. One must remember whatever the method of calculation the resultant date is but the centre of a fortnight or any day of which labour may ensue and many cases will be found to terminate a few days earlier or later (R W Johnstone). Appreciation of this fundamental fact, a practitioner thus tacitly accepts contract to make himself available for the labour whatever the ensuing date.

Corrosive Drugs

Dr C M HEANLEY (Salisbury Rhodesia) writes: The recent articles (March 22 p 367, and May 10 p 640) in the *BMJ* on ferrous sulphate poisoning raise the question whether gastric ulcer can be produced by the custom of putting up corrosive drugs in tablet form. I think I have heard of haematemesis and melaena being caused by aspirin taken in solid form.

Bewilderment

Dr G C PETHER (Colchester) writes: Is it not time that an absurd situation such as is here described should be made impossible? A workman develops dermatitis while engaged in a process which may or may not be the cause of his trouble. He is treated by the factory doctor until the condition is nearly cured. He is then sent by the employers' insurance society to see consultant A. This gentleman is given no information about previous treatment, little information about the man's work, may gather little about his domestic hazards and does not notice his bad teeth. Somewhat later, when the condition has cleared up entirely, the workman is sent by his own solicitors acting for the trade union to consultant B. This gentleman is equally informed, or misinformed, of the relevant facts. In the name of all that is wonderful how can useful opinions be obtained in this way? The victim an uneducated man, is bewildered and made resentful by these absurdities. He has every reason to feel like this.

The Revolution in Anaesthesia

Dr G DUNDEDALE (Nanyuki, Kenya) writes: What a frightful picture of modern anaesthesia is given by Dr John Halton (April 19 p 543). Apparently nowadays we try to paralyse as many of the systems as possible with powerful synthetic drugs, and plug in as many more to counteract the ill effects of those already used. Having pushed the patient under with an intravenous barbiturate we carry on with a complicated apparatus delivering a variety of gaseous mixtures, and if we are incapable of providing adequate muscular relaxation we resort to a synthetic substitute for South American arrow poison, which paralyses the diaphragm in addition to every other muscle, so that the patient must then have forcible respiration through a bag and some other powerful stimulant to overcome the muscular paralysis. And there must be no anoxia! And 'after all this though the patient "can cough on the table, and will often speak" though "attached firmly to that particular form of anaesthetic apparatus favoured by the anaesthetist," he must be nursed in a steam tent and an adequate fluid intake assured—by the intravenous route if necessary. After reading this I sincerely hope that if I have to have a major operation, which God forbid, I may still find someone of my own generation who can give a decent inhalation anaesthetic such as I learnt from Sir Francis Shipway. There are, of course, operations where the ordinary inhalation anaesthetic is inapplicable and for which special methods must be applied.

Certificates

Dr H D FORBES FRASER (Crowthorne Berks) writes: Mr X laid up his car in 1940 and his tyres were commandeered. In 1947 he applied for a permit to purchase new tyres explaining that he had mislaid the receipt for the old ones which was also a promissory note for the permit to purchase. This problem puzzled the clerks in the Regional Petroleum Office. A totally inapplicable form was supplied. This form was taken to the appropriate office, and returned as being inapplicable. This situation stumped the clerk in the Divisional Petroleum Office. However after a great deal of explanation, and wishing to be helpful he advised Mr G to get a medical certificate. I wrote for him a certificate that in my opinion Mr G is entitled to replacement of his tyres and also a covering letter to the effect that I was willing to certify—what should I certify?—that he is alive or dead? ill or well? that I do or do not know the national importance of his business? What has it to do with a doctor anyway? Surely an affidavit about the lost form sworn before a commissioner of oaths would be a more appropriate procedure. I have received no guidance but Mr G has his permit on grounds of disability.

Obituary

A F BERNARD SHAW, MD FRCPI

Prof A F Bernard Shaw died on June 3 at Newcastle-upon-Tyne. He had been professor of pathology in the Egyptian University of Cairo and since 1938 in the University of Durham. He was also pathologist to the Royal Victoria Infirmary, Newcastle-upon-Tyne, and had been an adviser in pathology to the Emergency Medical Service.

Arthur Frederick Bernard Shaw was born on Aug 17, 1888, at Carrigmachattan, Co Dublin. Educated at Christ's College Blackheath, and at Trinity College, Dublin, he graduated in 1909, being senior moderator in natural science and winning the medal of the Dublin University Biological Association. After qualifying MB, BCh, and BAO in 1911 and acting for a short period as demonstrator of pathology, he was elected to a Rockefeller Fellowship. This enabled him to visit the Johns Hopkins University at Baltimore for postgraduate study. Proceeding MD in 1913, he became a Fellow of the Royal College of Physicians in Ireland in 1922, after a period as senior assistant medical officer of health at Cardiff. His appointment there was interrupted by the 1914-18 war, when he served as a medical officer in Gallipoli, Sinai and Palestine, and as pathologist to the 69th General Hospital with the Egyptian Expeditionary Force. In 1919 he was appointed lecturer in pathology at the University of Durham College of Medicine, and assistant pathologist at the Royal Victoria Infirmary and in 1926 he became honorary pathologist to the Princess Mary Maternity Hospital, Newcastle-upon-Tyne. For his services to Egyptian medicine as professor of pathology at the University in Cairo from 1933 to 1938 he was made a Commander of the Order of the Nile. He was a member of the Pathological Society of Great Britain and Ireland and was responsible for many papers on pathology and particularly on haematology, which appeared in this *Journal* and in other medical journals.

He had been a member of the British Medical Association for many years and was vice-president of the section of pathology and bacteriology at the annual meeting in 1933. He was also president of the Egyptian Branch in 1938.

J C S writes: We are yet too near to Shaw's death and too much in the shadow of his illness to measure his greatness. But greatness it was, both of character and of mind, and the nobility of the one and the depth of the other will be known only to those whom he taught or with whom he was intimate, for he was a reserved and modest man given much to quiet meditation. His interest in his subject was influenced greatly by his early training in classics and biology, by his passion for truth and logic, and by his abundant scholarship. His was indeed the most cultured mind of any man I have ever known. Shaw's achievements can be measured by knowing something of the man. He had a stern but noble countenance covering a modesty which was at times embarrassing. Deeper still lay a generosity of heart and warmth of feeling which were revealed in a smile of great charm and in acts of exquisite courtesy. He loathed self-seeking and insincerity and was suspicious of Anglo-Saxon compromise. In aesthetics he was relatively insensitive to the visual arts, but vividly sensitive to the form and function of words. There is little wonder that his lectures were unforgettable. They were precise, sincere and eloquent with the right and unusual word always coming to his aid. He saw his pathology as part of man's whole struggle with his environment, but would at times laughingly confess that many of its evidences came near to metaphysics. Devoted to the scientific method and concerned about the function of the university in the modern world, he was intolerant of the compromises which would link commercial and professional interests to a university department, and was anxious to rid the teaching hospital of those burdens and arrangements which prevented it from doing its proper work. It appeared to him logical that a teaching hospital with the functions of conserving knowledge of advancing knowledge and of setting the highest standards of practice should be arranged, administered, and staffed entirely for those purposes and he saw the solution of this only by making these institutions university.

departments in the true sense of the term. He could argue these things with fervour but would cease from arguing at the first sight of fixed prejudice or blind ignorance.

Shaw's work in pathology covered three periods with a Rockefeller Fellowship year at Johns Hopkins in America interposed. The first was as a lecturer in Newcastle, where he came in 1919 from an early training in Trinity College Dublin and an experience in pathology during the war. His second period was as professor of pathology at Cairo, and the last again at Newcastle, where he held the chair until his death. In his earlier period at a time when he was impatiently busy with research, he worked under a burden of routine and teaching and in physical circumstances so detrimental that they are hard to look back upon. In spite of the interruptions of illness he completed work which was widely noticed, on the influence of the vasomotor action on the leucocytic count of peripheral blood on the diurnal tides of the leucocytes in man and on constitutional abnormalities of the leucocyte. In addition he added to our knowledge of the pathology of rheumatic fever, and of Riedl's thyroiditis in articles which are still standard references. In Cairo he had scope for the first time to create a department nearer to his desire. This he did in a way which was a testimony to his powers of organization and his originality, and he left it a monument to his efficiency and sense of justice, for which the Egyptian Government honoured him. In Egypt he made a notable contribution to the pathogenesis of pulmonary schistosomiasis and to the pathology of the spleen, but he was quickly absorbed in reviving the study of paleopathology with new techniques. Here also he found an outlet for his lifelong interest in anthropology and the history of civilizations. Some of his most memorable lectures were those in which he used his study and experience of the Egyptian civilization to illustrate his views on pathology and the course of civilized life. Shaw returned to Newcastle as professor of pathology in 1938. The war was quickly on us but in spite of difficulties he was able to infuse activity into builders and architects to commence a building which would become an institute of pathology within the grounds of the Royal Victoria Infirmary, where pathological anatomy, experimental pathology, biochemistry, and bacteriology would have their place. This was another fruitful period of his life in spite of the inclemencies of war and interruptions of illness. His teaching and his influence then reached their full maturity. Shaw was a lovable man. Uncompromising in his conception of good and evil, of truth and untruth, he may have appeared obstinate at times, but the tragedies of the modern world saddened him and he saw no way out except by combining reason with science and with that experience of things which we call culture. He lived as near to his own high conception of life as any man could. How strict and distinctive that conception was is known to his friends. By that he will be judged and remembered.

D. J. MACKINTOSH, CB, MVO, MB, FRSED

Dr Donald James Mackintosh for forty-five years medical superintendent of the Western Infirmary, Glasgow, died on June 12. He was appointed consultant superintendent and succeeded by Dr Loudon MacQueen as medical superintendent on Jan. 1, 1937.

Dr Mackintosh, who was born in the parish of Shotts, was educated first in his father's school and later in Madras College, St Andrews. A student of Glasgow University, he qualified M.B., C.M. in 1884. He was house-surgeon at the Glasgow Eye Infirmary and later one of the resident medical officers at the City of Glasgow Fever Hospital. He was the senior resident there until he was appointed medical superintendent of the Victoria Infirmary at its opening in 1890. Two years later he became medical superintendent of the Western Infirmary and began then to build up his great reputation as an authority on hospital administration and construction. Thus, at the request of the South African Government, he went out to the Cape to advise on the construction of a large new hospital. He was also one of the advisers consulted during the reconstruction of the Royal Infirmary and the Royal Hospital for Sick Children at Glasgow.

Dr Mackintosh was largely responsible for the organization and equipment of the Scottish National Red Cross Hospital

which served at Kroonstadt during the war. Later, when the Territorial Force was instituted, he was appointed colonel of the 3rd Scottish General Hospital, with the colonel. On the retirement of the late Sir G. Mackintosh, he was appointed A.D.M.S. of the Lowland Division in 1914, he was supervising the administration of all military, war, and Territorial general hospitals in the Glasgow area. Col. Mackintosh's services in connection with the volunteers of the Territorials, and ambulance work, his appointment as Officer in charge of the 1st Transport Company, Royal Army Medical Corps. He was a member of the Council and Executive of the Scottish Branch of the British Red Cross Society, chairman of the Council of St. Andrew's Ambulance Association, and chairman of the medical and equipments committee of the Scottish National Red Cross Hospital.

Dr Mackintosh had been a member of the British Medical Association for almost sixty years. He served as a member of Council in 1908 and again in 1911, after being a representative at the Annual Representative Meetings in 1907 and 1908. In 1915 he was president of the Glasgow and West Scotland Branch, and in 1920 he was appointed to the Scottish Consultative Council. At one time he was vice-president of the British Hospitals Association, honorary secretary of the Association for the Registration of Nurses in Scotland, and a member of the council of the College of Nursing.

Dr Mackintosh's varied career brought him many honours and distinctions. For his work during the 1914-18 war he was made C.B. He was also a member of the Victorian Order, an honorary associate of the Order of St. John of Jerusalem in England, and a Knight of Grace of that Order. In 1912 his own university conferred on him the honorary degree of LL.D. Early in 1929 the Secretary of State for Scotland made him a member of the Central Liaison Committee for Voluntary Hospitals in Scotland. Later in the same year he was appointed a Deputy Lieutenant for the City of Glasgow.

Dr GWILYM LLEWELYN PIERCE, of Abercynon, Glam., died on May 14 at the age of 56. The elder son of the late Dr. Hugh Davies-Jones, who gave his children an old family name, Dr. Pierce was born at Llangollen and came to live at Mountain Ash when his father succeeded to the practice of his brother the late Dr. D. Davies-Jones, in 1903. Educated at Dinglewood School, Colwyn Bay, he qualified at Edinburgh in 1914, and served in the R.A.M.C. in the 1914-18 war until he was invalided. He then joined his father in practice for a short time, but took service in the Merchant Navy, in which he remained until 1919, when he returned to Mountain Ash. On his father's death in 1921, he set up practice at Penrhynceiber, leaving his younger brother, Dr. Howell Pierce, in the family practice. In 1932 he again broke new ground and established himself in practice at Abercynon, where he remained until his death. From the outset of his career Dr. Pierce identified himself closely with all aspects of public life, and was formerly High Constable of Miskin Higher. In the field of first aid he was a tireless worker, carrying on in the tradition of his family, his uncle having first introduced the movement into the Aberdare Valley. At the time of his death he was Commissioner of the Order of St. John for the district, and was soon to have been the recipient of further honours. He was a Freemason and a member of St. Paul's Cathedral Lodge. He is survived by his wife and three children, the elder daughter a medical student at Edinburgh.

J. G. J. writes: Gwilym Pierce was a great B.M.A. man. He was treasurer of the North Glamorgan and Brecknock Division and had been its chairman; he was also vice-chairman of the Local Medical War Committee. But perhaps more important than these and other offices which he had held was the great enthusiasm and energy he brought to Association affairs. Gwilym, as he was affectionately known, was always present whether at Divisional Executive, Branch Council, or Glamorgan Panel Committee meetings and always his contributions to the discussions were penetrating, realistic, and honest. We have lost a grand colleague, but his work for the Division will endure as an inspiration to those who remain. Gwilym Pierce was a family doctor, and it was as such that he achieved his greatest success. The esteem in which he was held by his patients, and indeed by the whole community, was most revealing, and at Mountain Ash on May 17 great crowds bore witness to the unique position which he held in the affections of the people.

HOSPITALS LIABILITY FOR A PATIENT'S PROPERTY

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

Hospitals take charge every day of the personal belongings of many hundreds of admitted patients and it is surprising that the question of their responsibility for the safe keeping of this property so rarely comes before the courts. A lady was admitted as a patient to the St Pancras Hospital, which is maintained by the London County Council as part of their statutory duty. The hospital authorities took charge of some jewellery and a cigarette case which she brought with her and stored them with hundreds of other articles in envelopes stacked on the floor of a room which an expert burglar could enter without difficulty. The patient's sister wrote asking for confirmation of the contents of the patient's handbag, mentioning a diamond ring and clip and asking where these were deposited. The letter was not answered, apparently on the ground that the hospital did not give receipts for property taken. The patient's property was stolen, probably by a burglar. The patient sued the LCC for the return of her property or its value and damages for its detention, alternatively for damages for conversion, negligence or breach of duty.

Mr Justice Henn Collins said¹ that the degree of care expected of the Council's employees depended on whether they were 'gratuitous bailees' or received something for taking care of the property. They had a statutory duty to receive the patient, and it was a necessary precondition on their part to take possession of all the property she brought. They were in a position to recover all the expenses to which they were put, including the expense of keeping her property and entering it in a book. If a bailee was compensated for his pains he was bound to take at least such care as men of common prudence would take. Some measure of the degree of care required in this case had been provided by witnesses from the hospital who said that if they had realized that the articles had been so valuable they would have put them in the safe. The judge thought the hospital authorities were wrong to assume, as seemed to have been their practice, that the articles which they received were all trumpery. They admitted persons of the higher as well as the lower income groups, and there was no presumption that patients' property was not of value. If the authorities chose to treat it as worthless or as offering little temptation to thieves they took a risk on themselves. Much of the property which fell into their hands was obviously of little value, but a degree of care which was reasonable in the custody of articles which offered little temptation was not reasonable in that of articles which might offer more temptation. They had been warned that the property contained diamonds, and there seemed to have been some failure in the administration which prevented notice that the articles must be considered valuable from reaching those concerned. The LCC were therefore liable. In awarding damages his lordship held that they must include purchase tax, for this must be paid if an article were bought retail. The tax was a real addition to the price which had to be paid to replace the lost articles. He thought the proper value of the ring was £700 and of the clip £900, to which must be added the agreed price of £40 for the gold cigarette case—a total of £1,640, for which he gave judgment.

Comment

This decision suggests some interesting questions. Presumably if the patient had entered a voluntary hospital and paid nothing for her maintenance, the hospital would have been a gratuitous bailee and have been liable only for the results of gross carelessness. Payment for a bed in a voluntary hospital would presumably make the hospital a bailee for value, would payment of a contribution assessed by the almoner do the same? And what will be the position under the National Health Service?

Medical Notes in Parliament

PENICILLIN BILL

The Second Reading of the Penicillin Bill, which has already passed the House of Lords, was moved in the House of Commons on June 9. Mr ANEURIN BEVAN said that while penicillin was in short supply its purchase and distribution had been controlled by Defence Regulations. As soon as it had become obvious there was enough of this substance for general use the Government had to decide whether control should be continued. The view of the Government was that if control were continued it should be by a Bill passed by the House of Commons. Persons who had special knowledge about this substance were unanimous that there would be great danger to the public health if it were unrestricted in sale and consumption. They knew that if it were consumed over a long period in small quantities it would establish in the organism a resistance to its beneficial effects. It was highly undesirable that this valuable substance should be the plaything of quacks, sold as penicillin lipstick, penicillin rouge, and penicillin powder. It would be appalling if as a consequence of misuse, the population might receive no advantage from it because it would have developed resistance in those who took it. The decision therefore was that a short Bill would empower the Ministry of Health to control the sale and distribution of penicillin. The Bill was concerned only with the sale of the drug to the individual consumer. The Government did not wish to impose controls on the sale of penicillin in bulk or for export. It was not afraid of any shortage of supply. The Bill laid down that penicillin could be given only on the certificate of a qualified medical practitioner or veterinary surgeon.

"Great Expectations"

The Bill also took power to deal with other drugs where control might later be found to be necessary and to which the same definition applied. One called streptomycin had caused Mr Bevan considerable trouble. Great expectations had been carelessly aroused about it, but the Ministry of Health knew that in some instances this drug had caused definite harm. In other instances although a healing effect had been claimed that had not been established. Other investigations of an analogous kind were going on which, if they proved successful, would transform the whole field of medicine, but the Government was anxious that when these were perfected it would possess power to prevent their thoughtless consumption and commercial exploitation in a manner injurious to the public. Therefore the Bill took power to control those substances by Regulation after the Ministry had received the advice of the Medical Research Council about them. When the Bill went into committee he would move amendments dealing with some of the criticisms which had been made in the House of Lords.

Sir JOHN MELLOR commented on the fact that the control of the Ministry of Supply over penicillin on the ground of scarcity had been maintained after the scarcity passed away. He described the Bill as a pretty tall order. To control a therapeutic substance which could not be described as a poison or a dangerous drug was a novel step. While some measure of control should be retained Parliament should be careful to see it did not go beyond what was necessary and was not retained longer than was necessary. He asked whether the Medical Research Council had been consulted on the provisions of the Bill. He gathered that medical opinion had not yet crystallized in this matter. It was impossible at present to know how far it was necessary to control the use of penicillin and for that reason he would move in committee to limit the operation of the Bill to five years. In a recent debate Col. Stoddart-Scott who was a qualified medical practitioner, said that penicillin toothpaste and ointment ought to be free of control.

Mr BAIRD said the whole of the dental profession thought that would be completely wrong and would cause disaster.

Dr HADEN GUEST said penicillin, when used in the wrong way became a very dangerous drug because what was called 'penicillin resistance' could be built up. That situation had already arisen in Japan in regard to certain diseases, and the people concerned—in this case Service men—were no longer helped by penicillin when they fell victim to disease. He assured Sir John Mellor that representatives of the medical profession in the Services agreed the control of penicillin must be rigid or it would lose its effect and cease to be a remedy.

"Freedom to Doctor Oneself"

Mr Linstead welcomed the Bill but said there was a considerable onus on the Minister to prove his case. Freedom

¹ *Martin v. LCC* (1947) 1 All E.R. 783

At this point the debate stood adjourned, although an agreement had been made to take the Second Reading that night.

The Bill was then read a second time and sent to a committee of the whole House.

Mr AELWYN BEVAN said in 1939 there were 104 day nurseries in Eneland and Wales. In 1944 the number increased to 1 550 with places for 71 000 children. In 1947 these figures fell to 900 nurseries with places for 44 000 children but in the meantime 370 nursery schools had been provided for 19 000 children. These figures showed a higher proportion of women in industry and of nursery facilities than in time of war.

Government regarded the day nurseries as a better solution than day camps. It was panicked into recruiting a consequence it caused neglect of 150,000 children in the infant class and about 250 wartime nurseries so they were making some headway the need was proved. They gave towards the cost of nursery schools increase the proportion. He was in regard to creche facilities legislative power at present, and no places for young children. He was possible to provide crèches the mother could look in during the take it home with her straight away.

DEATHS IN THE SERVICES

Lieut Colonel M. M. LOVSEY died at his home in Bradninch, Devon, on May 8 at the age of 74. He was the fifth son of the late Luke Lovsey of Hampstead Norris, Berks and was educated at Cheltenham College and Charing Cross Hospital. He qualified in 1896 and was commissioned in the R.A.M.C. in 1898, returning in 1922. He then went into general practice at Bradninch, returning from that in 1937. He served with distinction during the first world war, being twice mentioned in dispatches and awarded the D.S.O. and the Greek Meritorious Medal. During the second world war he served continuously on medical boards and in the Home Guard. He took a great interest in local government and was for a long period on the Wokingham Rural District Council.

Surgeon Rear-Admiral H. M. WHELAN, formerly officer commanding the Royal Naval Hospital, Plymouth died on May 27, at the age of 57 after a long illness. Hamlet Mark Whelan was a son of the late Fleet Surgeon J. H. Whelan, educated at University College, Cardiff and the London Hospital, he qualified in 1912. He joined the naval medical service the same year and served in the cruisers *Essex* and *Adventure* and during the 1914-18 war at the R.N. Hospital Chatham. Subsequently he was in charge of the R.N. Hospital at the Cape of Good Hope, which appointment he retained until 1943, when he became Surgeon Captain (surgical division) of the R.N. Hospital Plymouth. In 1944 he was promoted rear admiral and became Principal Medical Officer Western Approaches. He was appointed an honorary surgeon to the King in 1946.

In this column of the *Journal* of June 7 (p. 830) Sir Henry L. Tidy, K.C.B. should read Sir Henry L. Tidy, K.B.E.

EPIDEMIOLOGICAL NOTES

Smallpox

Contacts remain under surveillance at Barnsley C.B., Bilston U.D. and Wakefield C.B. The last patients were removed on June 4 and the cropping period for a new generation has been entered, but no further cases have been reported at the time of going to press.

At Barry U.D., Glamorgan, a woman aged 28 was removed as a case of suspected smallpox on June 13 and the usual precautions were taken. The diagnosis is still in doubt.

The diagnosis in the initial Wakefield case has now been confirmed by the recovery of variola virus on egg culture.

The last case was removed from Sheffield on May 21, and there are good reasons for believing that the outbreak there has terminated.

The period of surveillance of contacts at Coseley expired on June 16 without further incident. The outlook here is hopeful.

Discussion of Table

In *England and Wales* infectious diseases were less prevalent. There were falls in the incidence of measles 516, whooping-cough 222 and scarlet fever 96.

The largest decreases in the notifications of measles were Essex 240, Worcestershire 152, Lancashire 142, and Kent 75, the largest increases were Glamorganshire 164, Isle of Ely 83, Hertfordshire 63, and Somerset 53. Small decreases in the incidence of whooping-cough were recorded in most areas, and the largest declines were Kent 48 and Essex 32. In contrast to the general trend large rises in the number of notifications occurred in Yorkshire West Riding 75 and Middlesex 45. There were no changes of any size in the local returns of scarlet fever. The only variations of note in the returns of diphtheria were a decrease in Lancashire 17 and an increase in Durham 17.

The notifications of smallpox were 6 higher than in the preceding week, giving the largest weekly total for recent years. The 14 cases were distributed in three areas, Yorkshire West Riding, Barnsley C.B. 11, Sheffield C.B. 1, and Staffordshire Coseley U.D. 2.

In *Scotland* decreases were recorded in the notifications of whooping-cough 42 and acute primary pneumonia 15, the only increase being that for measles 36. The notifications of cerebrospinal fever in Glasgow rose from 15 to 29.

In *Eire* the incidence of measles increased by 28 while a fall was recorded for whooping-cough 12 and diphtheria 13. The rise in cases of measles was mainly contributed by Dublin C.B. with an increase of 22.

In *Northern Ireland* the only change of any size in the trends of infectious diseases was an increase of 13 in the notifications of measles.

Week Ending June 7

Notifications of infectious diseases in *England and Wales* during the week included scarlet fever 730, whooping-cough 2050, diphtheria 196, measles 1353, pneumonia 467, cerebrospinal fever 63, acute poliomyelitis 22, dysentery 53, smallpox 7, paratyphoid 16, typhoid 2.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended May 31.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) *England and Wales* (London included) (b) *London* (administrative county) (c) *Scotland* (d) *Eire* (e) *Northern Ireland*.

Figures of Births and Deaths and of Deaths recorded under each infectious disease for (a) The 126 great towns in *England and Wales* (including *London*) (b) *London* (administrative county) (c) The 16 principal towns in *Scotland* (d) The 13 principal towns in *Eire* (e) The 10 principal towns in *Northern Ireland*.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1947					1946 (Corresponding Week)

* Measles and whooping-cough are not notifiable in *Scotland* and the return are therefore an approximation only.

† Includes primary form for *England and Wales* (*London* (administrative county) and *Northern Ireland*).

‡ Includes puerperal fever for *England and Wales* and *Eire*.

Medical News

West London Hospital Medical School

The youngest of the undergraduate medical schools, that of the West London Hospital at Hammer-smith, will close shortly, and places will have to be found elsewhere for students who had intended to do their clinical training there. From a small beginning in 1937 with a few women students who were unable to obtain their clinical training at the schools where they had pursued a pre clinical course, it gradually expanded to take 80 to 90 students, still mostly women, from UCH, King's College Hospital, and Oxford and Cambridge. No men have been admitted since 1941. The status of undergraduate teaching school within London University has been sought, but was finally turned down in March of this year, the chief reasons being that facilities for pre clinical training are not available and to provide them would require considerable rebuilding, and additional staffing and expenditure. This decision is in accordance with the Report of the Goodenough Committee, which recommended the expansion of other medical schools and the ultimate closure of the West London. The future of this successful endeavour to provide opportunities for more women to qualify as doctors may lie within the British Postgraduate Federation, and it is envisaged that the school should become a centre for the training of specialists in medicine and surgery.

New Research Unit

The Medical Research Council is setting up a new research unit on the physiology of vision. Prof. H. Hartridge is to be the Director.

Confinements under NHS (Scotland) Act

Criticism has appeared in the Press and elsewhere that under the National Health Service Act women confined in their own homes would be unable to have a doctor present, and that if complications arose the patient would have no choice of doctor. It has also been suggested that women would be expected to go to maternity hospitals during confinement to obtain the benefits of the new scheme. These points were raised at the annual meeting of the Central Council of Scottish Women's Rural Institutes and were the subject of a letter addressed by the Council to the Secretary of State for Scotland. The Secretary of State's reply points out that the criticisms are without foundation. A woman may choose what ever doctor she wishes to attend her at home, and he will also be responsible for antenatal medical examination, treatment, and supervision. Furthermore, if a woman wishes to be confined at home, she may be.

New Journal of Nutrition

The first part of a new quarterly, the *British Journal of Nutrition* of the Nutrition Society, will appear shortly. It will incorporate the *Proceedings of the Nutrition Society* and publish original work on all branches of nutrition. Papers for publication should be sent to Dr. S. K. Kon (British Journal of Nutrition), National Institute for Research in Dairying, Shinfield, Nr. Reading, Berks. The editorial board will consist of D. P. Cuthbertson, J. N. Davidson, R. C. Garry, G. Graham, J. Hammond, E. M. M. Hume, S. K. Kon (chairman), I. Leitch, W. C. Miller, F. Yates, B. S. Platt, and J. A. B. Smith. Subscription rates for non members of the Nutrition Society are £3 per volume of four quarterly parts, separate parts will cost £1 each. Subscriptions and inquiries should be addressed to the Cambridge University Press, 200, Euston Road, London, NW 1.

Royal College of Midwives

The King has commanded that the College of Midwives, founded in 1881 and incorporated in 1886, shall be entitled the Royal College of Midwives.

Reduction of Local Authority Staffs

The Government's White Paper, the "Economic Survey for 1947," pointed out the necessity of expanding the nation's labour force and assumed a reduction in the numbers employed in national and local government. A circular from the Ministry of Health to local authorities invites them to reduce the numbers of their employees as much as possible.

Relief of Widows and Orphans

The annual general meeting of the Society for Relief of Widows and Orphans of Medical Men was held on May 21 with the president, Dr. R. A. Young, in the chair. The court of directors for the ensuing year was elected. The resignation of Dr. Blackett as secretary of the society was received, and in appreciation of his services as secretary for a period of 42 years Dr. Blackett was elected a vice president. The accounts for the year ending Dec 31, 1946, were presented. The total amount distributed in grants during 1946 to 52 widows was £3,912 10s., and, in addition, a Christmas present of £20 was made to each widow, making the total amount distributed £4,952 10s. It was reported that the membership of the society was 281, of which 160 were life members and 121

ordinary members. Particulars of the society may be obtained on application to the secretary, 11, Chandos Street, London, W 1.

First Woman President

The Pharmaceutical Society has elected as its president Mrs. J. K. Irvine, M.B.E., who is at present Superintendent of the Ministry of Health's South Eastern Pricing Office. She is the first woman president to be elected in the 106 years of the Society's history.

Convalescent Diabetics

Special convalescent facilities are now available for diabetic patients at the British Red Cross Convalescent Home, Burley on the Hill, Oakham, Rutlandshire (for men and boys), and at St. Mary's Convalescent Home, Birehington on Sea, Kent (for women and children). These homes educate diabetics to look after themselves and include training in giving injections, doing urine tests, and cooking. Further particulars may be obtained from the Almoner, Convalescent Homes, Diabetic Association, 9, Manchester Square, London, W 1 (Tel. Welbeck 6001).

Hospital Service Plan

The Hospital Service Plan, introduced five years ago by King Edward's Hospital Fund for London, has been extended to include an additional £1 is per week, cover for tonsillectomy previously excluded, and a choice of three different schemes.

Zodiac

The Aberdeen University Medical Society has just issued the first number of its journal published under the title of *Zodiac*. It is intended that this new publication shall appear twice yearly, in September and March.

Chartered Society of Physiotherapy

The Society of Physiotherapists, which was started fifteen years ago, has now been wound up, and as a result of discussion with the Chartered Society of Physiotherapy the latter society has agreed to accept bio physical assistants on the Society of Physiotherapists' sponsorship for enrolment on the CSP Register.

Medico Legal Dinner

The Medico Legal Society on June 12 held its first dinner since the outbreak of the recent war. Sir Frank Newson, of the Home Office, proposing the toast of 'Medicine and Law,' paid a tribute to Sir Norwood East and the medical profession for their services to the Home Office and announced that his Department was preparing a Criminal Justice Bill that would enable courts to take full account of an offender's mental condition. Lord Schuster responded, wondering whether the Bill would be too elaborate for those who would have to operate it. Sir Maurice Cassidy, pleading that he was 'the apotheosis of the dumb doctor,' spoke of the trouble caused by doctors and lawyers. Lord Moran proposed the toast of the Medico Legal Society, and admitted the way lawyers tore a patient apart to get at the essentials just as doctors dissected the body. Sir Norwood East, the President, responded. He recalled that the Society was 46 years old and continued to increase in numbers, while vigilantly maintaining its high standards. He reviewed some of its recent activities and concluded by referring to the device on the Society's journal—a woman symbolising Truth being drawn from a well by the hand of Medicine on one side and of Law on the other.

DDT Grit

A man and his wife, their two children aged 6 and 9, and a brother-in-law, were admitted to the Manchester Royal Infirmary at 6 p.m. on Sunday, June 15. They were suffering from diarrhoea and vomiting as a result of taking DDT mixed with grass. The man had helped his wife to make the grass as was his custom. Instead of stirring 2 tablespoonfuls of flour into 1 p. of grass he stirred in 2 tablespoonfuls of what was said to be pure DDT. This was kept in a similar type of tin to the flour. The grass was eaten about 3 p.m. by the five people, and the brother-in-law said a metallic taste at the time. Two hours later all five were sick with diarrhoea and vomiting, varying in severity according to the quantity consumed. The father who was fond of his own food consumed more than the others was the most affected. On arrival at the hospital they all complained of diarrhoea and sickness, the hands and feet. The only one of the five about whom no complaint was felt was the father. There was a good deal of diarrhoea, and the stomach tube on account of coughing. After one hour of coughing he was unconscious for a few moments. The mother, child, and the brother-in-law, all recovered rapidly and were able to return home later in the evening since they lived near the hospital. The father and one child were still complaining of diarrhoea, nausea and were detained for the night. Both had fully recovered by Monday morning. If this was pure DDT then the grass presumably contained about 10 p.p.m. Assuming that half of the grass was wasted by being left in the pan or on the plate and that two individuals may have consumed the equivalent of 1 p.p.m. of DDT more in the case of the father.

COMING EVENTS

Malaria Control

The annual malaria control courses for planters miners and others is to be resumed and this year will be held at the London School of Hygiene and Tropical Medicine, Keppel Street W.C., from June 23 to 27 inclusive. The lectures and demonstrations will be given from 10 a.m. to 1 p.m. each day. Arrangements will be made to give lectures on other subjects such as housing sanitation, etc. in the afternoons. The course is free. Applications to attend should be sent as early as possible to the organizing secretary, Royal Institute of Tropical Hygiene, Keppel Street, Gower Street, London W.C.1.

Nutrition and Bread

The Sanderson Wells Lecture will be delivered by Sir Jack Drummond D.Sc., F.R.S., at the Middlesex Hospital, W., on Tuesday, June 24 at 4.30 p.m. His subject is "The Nutritional Value of Bread." The lecture is open to all members of the medical profession.

Paddington Medical Society

The annual general meeting of the Paddington Medical Society will be held at St Mary's Hospital Paddington, W., on Tuesday, June 24 at 8.45 p.m., when the president, Dr L. Zeitline, will deliver an address on 'Humour in Medicine.' All medical practitioners are invited to attend.

Hygiene Congress

A Congress of School and University Hygiene will be held in Paris on June 25-29, under the auspices of the Ministries of Education and Public Health. Subjects to be discussed include the schooling of mental defectives, school meals, schools for visually defective children and corrective exercises. Doctors from abroad interested in school hygiene are invited to participate. Inquiries should be addressed to the secretary general of the congress, Dr P. Delteil, 46, Rue de Naples, Paris (8^e).

Faculty of Homoeopathy

A meeting of the Faculty of Homoeopathy will be held at London Homoeopathic Hospital on Wednesday, June 25, at 5 p.m. when Dr John Paterson will read a paper on 'Homoeopathic Philosophy Brought Up to Date.'

Medico Legal Society

A meeting of the Medico Legal Society will be held at 26 Portland Place, W., on Thursday, June 26, at 8.15 p.m., when the president will read a paper on 'Psychiatry and Degrees of Murder.'

Faculty of Radiologists

The annual meeting of the Faculty of Radiologists (45, Lincoln's Inn Fields, London, W.C.) will be held at Birmingham on Friday and Saturday, June 27 and 28.

Society for Endocrinology

A meeting of the Society for Endocrinology will be held at Guy's Hospital S.E. on Saturday, June 28, at 10 a.m., when a symposium on 'The Assay of Urinary Steroids' will be presented.

Lewis's Library and Bookshop

Messrs H. K. Lewis and Co., Ltd. (136, Gower Street, London, W.C.) have asked us to bring to the notice of our readers the fact that they have arranged a staff outing for Saturday, June 28, and that, in consequence, their premises will be closed on that day.

Association of Clinical Pathologists

The 38th scientific meeting of the Association of Clinical Pathologists will be held at the Sir William Dunn School of Pathology, Cambridge on Friday and Saturday, June 27 and 28. The programme is as follows: June 27 9.30 a.m., Dr K. S. Thompson, 'Chronic Thrombosis of the Hepatic Ostia' 9.45 a.m., Dr M. Bodian, 'Pulmonary Haemosiderosis' 10.10 a.m. Drs G. T. Cook and B. P. Marmion 'Gastro enteritis of Unknown Aetiology Outbreaks at Leicester and Oxford, 1944-7,' followed by a discussion to be opened by Dr R. Cruickshank 11.35 a.m. Dr H. Sisk (Prague) 'Lesser Known Histological Methods for Routine Use in the Laboratory' 12 noon, Dr R. M. Haines 'The Eye in Tuberculous Sclerosis' 12.15 p.m. Drs J. S. Mitchell and A. M. Barrett, Symposium on 'The Radiosensitivity of Tumours' 2 p.m. demonstrations 4.45 p.m. Dr J. E. McCartney 'The Use of the Electron Microscope in Bacteriology' 5.15 p.m., Presidential Address 'A Retrospect of British Pathology' June 28 9.30 a.m. Dr M. Hynes, 'The Leucocytic Drift' 9.55 a.m. Dr J. Ungar, 'The Antigenic Properties of Pertussis Vaccines' 10.15 a.m. Dr S. Seviat 'Saline Haemolysin Test for Streptococci' 10.30 a.m. Dr F. Vanicek (Pilsen), Report on 'Some Attempts to Simplify Diagnostic Methods in Clinical Bacteriology' 11.30 a.m. Dr A. Renshaw, 'Blood Protein Variations in Rheumatic Diseases, with Remarks on Technique' 11.50 a.m. Dr J. V. Wilson, 'Blood

Viscosity as an Index of Activity in Chronic Rheumatism' 12.10 p.m., Drs E. J. King and R. J. Garner, observations on 'The Colorimetric Determination of Glucose' 12.35 p.m., Dr C. E. Dukes 'Unsolved Problems in Genito urinary Tuberculosis' 2.30 p.m., Prof. H. R. Dean will conduct a party round the college and Dr R. Williamson will show some early medical books. Various demonstrations will be given from 2 p.m. on June 27 to 12 noon on June 28.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

Section of Urology—Thursday, June 26, 8 p.m. Clinico pathological Meeting.

Sections of Laryngology and Otolaryngology—Friday, June 27 Combined Summer Meeting at Brighton Meeting in the Nurses Lecture Room Royal Sussex County Hospital 10 a.m., Paper by Miss Winifred Hall and Mr John McGibbon 'The Association of Otitis Media with Acute Non specific Gastro enteritis of Infants' 2 p.m. Papers by Mr V. E. Negus 'Certain Anatomical and Physiological Considerations in Paralysis of the Larynx' Mr W. E. Archer 'The Treatment of Subacute Maxillary Sinusitis especially in Children' Film by Dr Hollinger of 'Bronchial Neoplasms' will be shown by Mr G. H. Bateman.

Sections of Laryngology and Otolaryngology—Saturday, June 28 Summer meeting at Brighton continued 10 a.m. Clinical meeting in Grant Ward, Royal Sussex County Hospital Discussion 11.45 a.m. Film and Demonstration Miss M. R. Dix and Mr C. S. Hallpike 'Pure tone audiometry in young children' A new technique.

POSTGRADUATE DIARY

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE—At West Medical Lecture Theatre, Edinburgh Royal Infirmary, Tuesday, June 24 5 p.m. Dr T. N. MacGregor 'Sex Hormones in Theory and Practice.'

LONDON SCHOOL OF DERMATOLOGY 5 Lisle Street Leicester Square W.C.—Tuesday, June 24, 5 p.m., Dr W. J. O'Donovan 'Occupational Dermatitis' Wednesday, June 25, 5 p.m. Dr C. W. McKenny 'Technique of X-ray Treatment (Part II).'

A clinico pathological demonstration will be held in the Meyerstein Lecture Theatre of the Westminster Hospital School of Medicine, Horseferry Road, S.W. on Monday July 7, at 5 p.m. when two cases of aplastic anaemia will be shown.

APPOINTMENTS

Miss Laura Margaret Dorothea Mill, M.B., Ch.B., has been appointed a Medical Commissioner of the General Board of Control for Scotland in place of Dr Kate Fraser who retired recently. Dr Mill has been in the service of the General Board of Control as a Deputy Commissioner since 1936.

Mr Daniel Limont, consulting surgeon at the Gilbert Bain Hospital, Lerwick, has been appointed an honorary member of the Association Française de Chirurgie.

Dr H. B. Lee, D.S.O., M.C., has been appointed a Nominated Member of the Executive Council of the Island of St. Helena.

HEWITT S. M.B. B.S. D.P.H. Deputy County Medical Officer for Herefordshire.

LONDON COUNTY COUNCIL.—The following appointments are announced at the hospitals etc. indicated in parentheses: Medical Superintendent A. Mitchell M.D. (St. John's) Deputy Medical Superintendents R. G. Thomas F.R.C.S. Ed. (Queen Mary's Hospital for Children Carshalton) J. Sharkey M.D. (Northern) R. D. Green M.D. (Paddington) F. R. Leonard F.R.C.S. (St. Leonard's) M. Twohey M.D. (New End) Senior Resident Surgeons I. A. Alexander M.B. Ch.B. (Hackney) E. C. Chitty F.R.C.S. Ed. (St. Stephen's) Pathologist A. Beck L.R.C.P.S. Ed. (Group Laboratory North western) Assistant Pathologists A. F. Mohun M.B. B.S. (Archway Group Laboratory) S. C. Dobson B.M. B.Ch. (St. Mary Abbeys Group Laboratory) Junior Assistant Pathologist R. Martlew M.B. B.Chir. (Lambeth Group Laboratory) Radiodiagnostician V. G. Peckar M.B. B.S. (Lambeth and St. Charles) Assistant Radiodiagnostician G. M. Ross M.B. Ch.B. (Hammersmith) Junior Assistant Radiodiagnostician J. M. Corral M.B. Ch.B. (Hammersmith) Assistant Medical Officers School Health Service G. K. Lim M.B. B.S. A. L. Throver M.B. B.S. Edith J. R. Parfitt M.D.

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender and should reach the Advertisement Manager not later than first post Monday morning.

BIRTHS

CAPPER—On June 3 1947 to Margaret (née Hutchinson) wife of J. I. Capper M.B. of Merthyr Tydfil a son.
ROSS—On May 24 1947 to Mary (née Long) wife of Kenneth Aird Ross M.B. Ch.B. 74 Clare Court Judd Street W.C.1 a son.
TAYLOR—On May 24 1947 to Dinah (née Lidsier) wife of Kenneth H. Taylor F.R.C.S. a son.

MARRIAGE

POLLITT—ATTWOOD—On April 30 1947 at Castle Church Stafford Peter G. H. T. Pollitt M.B. Ch.B. to Gwendoline Attwood.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Electronarcosis

Q—Could you give me information or references concerning electronarcosis in the treatment of psychotics?

A—Electronarcosis is a modification of electric convulsive therapy. The machine used is different in that it has a device by which a continuous current can be run through the brain, since changes in the patient's resistance are compensated for by raising or lowering the voltage automatically. It is described in articles by Frostig *et al* (*Arch Neur Psychiat* 1944, 51, 232), and Tietz *et al* (*J Nerv Ment Dis* 1946, 103, 2, 144). The treatment was started at hospitals in the neighbourhood of Los Angeles. The technique in man is to give the patient a current of about 180 milliamperes for half a minute and thereafter to decrease it gradually to about 65, gradually raising it again to 100 or 120 milliamperes. The total treatment lasts seven minutes. The current is much less than that given in electric shock (400 to 1,200 milliamperes), and animal experiments have shown that no irreversible changes occur in the brain. During treatment the patient remains in a tonic state for the first half-minute, when respiration is inhibited and thereafter, by gradual reduction of the current, falls into a quiet narcotic state in which the muscles are hypertonic with flexion at the elbows and extension of the knees. The treatment is given three times a week for a month. A second course lasting a month can be given after a week's rest where recovery is not complete.

It is claimed that the treatment is successful in cases of schizophrenia where ECT is relatively unsuccessful, and that the results are equal to those of insulin coma therapy. Only 47 cases, however, have been published to the writer's knowledge but more work is expected. In 1946-7 treatment by electronarcosis has been started at the West London Hospital, St James's Hospital, Portsmouth, Guy's Hospital, and Sutton Emergency Hospital.

Pink Disease

Q—Would you suggest a method to quiet a very irritable child suffering from pink disease? It has the typical rash all over its body. Chloral hydrate and phenobarbitone 1½ gr (32 mg) have had no effect. The parents are getting no sleep and are becoming desperate.

A—In the first place remove the parents' despair by explaining why the child is miserable. They will be encouraged by this. Tell them that the child is suffering from an intolerable burning, itching sensation which is most exquisite in the fingers, toes, tongue, and perianal area, that the disease will run its course in three to six months, that the child's recovery will depend on the constant care and nursing which they themselves give it and which they can give far better than any hospital. Give them heart by saying that when the child recovers the credit will be entirely theirs. If the mother is losing too much sleep (which is not probable, because the sleep requirements of mothers fall to very little when their own children are ill) get the granny or a neighbour to come in and help her from time to time. Clothe the child with linen or silk next to the skin. Do not give hot drinks. Feed the child on ice cream if necessary. Walk the floor with the child, and wheel it out of doors in a pram as much as possible. Use cooling lotions and frequent cool baths. Explain that it is satisfactory if the child sleeps only in short periods of twenty or thirty minutes, that will suffice. When you have done all these things consider the use of sedatives, but use them wisely. A child ill with pink disease may get bronchopneumonia if drugged too much. Every other day or so give enough barbiturate to make the child sleep for about two hours. Certainly 1½ gr of phenobarbitone will not suffice. Try a bigger dose. Finally, do not admit the child to hospital.

Trigeminal Neuralgia

Q—A woman aged 65, who was surgically relieved of an intractable tic douloureux ten years ago now has a recurrence on the other side. As she will not contemplate surgery again can you inform me of any recent advances in medical treatment?

A—There are no recent advances in the medicinal treatment of trigeminal neuralgia. For the purely temporary relief of a paroxysm of pain there is, of course, the inhalation of 5 to 10 drops of trichlorethylene from a handkerchief. This has to be done cautiously as it may produce syncope. Surgical treatment offers the only permanent cure, and the newer techniques are certainly an improvement on the old. The physician might well feel justified in pressing surgical treatment in such a case. Alcoholic injection of the nerve may be regarded as a rather inadequate compromise.

Sexual Frigidity

Q—A happily married woman aged 36 with two children complains of complete absence of libido. She is physically normal and healthy and there is no apparent psychological cause. A prolonged course of chorionic gonadotrophin has not improved the condition. Is there any safe aphrodisiac I can give her and would it be suitable for use in cases of male impotence?

A—Although a psychological cause for the frigidity is no apparent, a physical cause is not likely for if there was an endocrine upset there would be other evidence of its presence. The question does not state whether the frigidity has always been present or whether it is a recent development. Among the possible factors to be looked for are fear of pregnancy and an unsatisfactory method of contraception. Drugs reputed to have an aphrodisiac action are rarely of any value and the same is true of hormones except where there is gonad deficiency. In such a case oestrogens for the female and testosterone for the male, are preferable to gonadotrophin.

Cholecystography after Cholecystitis

Q—Is cholecystography contraindicated within two to three weeks after an acute attack of cholecystitis on account of possible damage to the liver?

A—As a rule cholecystitis is a local infection, the liver is not much affected unless there is accompanying cholangitis. Therefore there should be no risk of damaging the liver by taking a cholecystogram three weeks after an acute attack of cholecystitis.

Undulant Fever

Q—I have a patient with undulant fever of whom two pathological investigations have been made. The first pathologist found a titre of 1/125 for *Br. melitensis* *Br. abortus* and the second (ten days later) found titres of 1/500 for *Br. abortus* and 1/150 for *Br. melitensis*. In view of these conflicting reports how can I cure the fever?

A—Would the questioner have been in any way in a better position to cure this patient if the two reports had agreed? The treatment of undulant fever due to either species of *Br.* is notoriously unsatisfactory. They are usually highly resistant to penicillin, even streptomycin has given disappointing results in spite of *in vitro* susceptibility to this drug. A course of one of the sulphonamides is the only appropriate form of chemotherapy, this often appears to shorten the duration of the disease. If the infection was acquired in this country it is almost certainly due to *Br. abortus* and the findings in the second report quoted are typical—a high titre for *Br. abortus* organism and a lower for the other, owing to their close antigenic relation.

Treatment of Catarrh

Q—Is there any hypodermic treatment for catarrh unrecognized, for catarrh?

A—Presumably hypodermic treatment means systemic treatment by injection. There is no medical treatment of catarrh administered either orally or by the hypodermic route. As for unrecognized catarrh...

general treatment of cataract, these are as numerous as the practitioners who administer them. They have no scientific basis. The least confused would appear to be some method of antient treatment based on the injection of lens matter. A fairly prevalent method is the use of sodium iodate drops. There is no reason to believe that this is any less futile than the other methods.

Keloid Formation and Skin grafting

Q—*A girl aged 13 who is having skin grafts has proved to be a keloidal subject. The donor sites have formed such poor tissue that it is doubtful whether further grafts can be taken. Have skin grafts been successfully taken from one person to another?*

A—The patient whose donor site has become keloidal presents a problem well known to all plastic surgeons. As a rule donor sites of split skin grafts can be used several times, but where keloidal tissue has formed—and this may occur even where the thinnest skin grafts are removed—great difficulty may be experienced in obtaining enough skin. Usually with the passage of time the keloids subside. Carefully graduated doses of x rays are useful. Skin grafts from another person do not help, for though they occasionally take for a short period, they usually disappear. Cross grafting of skin is not satisfactory except in the case of identical twins.

Urticaria

Q—*A female aged 58 had urticaria three years ago lasting nearly two years. Skin tests failed to show sensitivity to any food. Recently another attack started. Can she be desensitized? What treatment would you recommend?*

A—Search should be made for a focus of infection. Failing this, stilboestrol is well worth trying. In the allergic type, foods and drugs are the commonest causes. The most likely foods are egg, milk, wheat, fruits, and fish. As skin tests are unreliable in urticaria, food sensitivity can be tested only by trial dieting, excluding from the diet the food or foods suspected for a few weeks and then restoring them and noting the effect. If a specific allergic cause is found, elimination rather than desensitization is the treatment of choice. Non specific treatments are by vitamin K and autohaemotherapy. 'Benadryl' in doses of 50 to 150 mg gives symptomatic relief in about 80% of cases but its tendency to cause drowsiness necessitates the first few doses at least being taken at home, preferably in the evening.

NOTES AND COMMENTS

Cystine Stones—Dr W. M. CHESNEY (Birmingham) writes. In the answer to the question on cystine stones (May 31, p. 794) it is stated that there is no known method by which they can be dissolved after they have formed. The following brief account of the complete disappearance of a massive collection of bilateral cystine calculi may be of interest. X-ray of the urinary tract of a woman aged 25 in October, 1934, revealed a massive collection of bilateral renal calculi. She was then seen by two distinguished urologists who diagnosed cystine stones and prescribed a low protein diet and alkalization of the urine. They also with some hesitation decided that an attempt should be made to remove the stones from one kidney. From the x-ray film the right kidney appeared the more operable and in March 1935, one of them removed during a tedious operation about twenty stones from that kidney, reluctantly leaving a considerable number behind. X-ray four months later (July, 1935) showed a mould stone shadow in the left kidney pelvis and multiple stone shadows in the right kidney. Subsequently a skragraph was taken every year up to 1939 (inclusive) and again in January 1941, and in October, 1944. The films showed a progressive diminution of the calculi up to 1939, when the right side was reported by the radiologist as practically clear and the original large mass on the left had become a very small shadow. On the films of 1941 and 1944 there was no shadow present to suggest a urinary stone. I am in possession of all the x-ray films except the first (October, 1934) which was unfortunately lost at the time of the operation. Dr Harold Black, of Birmingham, was the radiologist throughout and the sentences in inverted commas are extracts from his reports. Reproduced is the film of July 1935 (four months after operation). The stone shadows on films of later date are so small as to be indiscernible on reduced photographic reproduction of the films. The patient adhered more or less to a low protein diet until the onset of the late war when she practically abandoned it. Where a choice in diet is still available she generally selects the articles of lower protein content. At first she took a pot cit and sod

bicarb mixture and frequently tested her urine for alkalinity. For several years now she has taken sod bicarb only, usually two level teaspoonfuls daily, her urine being tested for alkalinity occasionally.

Presumably the prolonged alkalization of the urine was the chief operative factor in the dissolution of the calculi. It should be added that she became pregnant (first pregnancy) in 1938, refused early evacuation of the uterus (advised as a result of renal function tests), had a normal pregnancy, and gave birth to a healthy female child in 1939.

Discussion on Homosexuality Correction—Dr H. MANNHEIM (London, WC2) writes. My attention has been drawn to a report on the joint meeting of the Medico Legal Society and the Section of Psychiatry of the Royal Society of Medicine published in your issue of May 17, 1947 on p. 691, where I am quoted as having stated that homosexuality came under ecclesiastical law 'from Henry VIII until 1763'. I am afraid the words which I have put in quotation marks are a misquotation. What I have actually said was that homosexual activities had been punishable in this country only as an ecclesiastical crime up to the time of Henry VIII (1533). I did not mention the year 1763 at all.

INCOME TAX

All inquiries will receive an authoritative reply but only a selection can be published.

Postgraduate Study

I T has expended £1,000 on a three months' visit to the U.S.A. for the purpose of postgraduate study. Can he claim a deduction for such expenses—e.g. as incurred for "Scientific Research"?

•• No. Such expenses the purpose of which is to add to professional knowledge and skill and to improve earning capacity are regarded as an outlay of capital and not as an "income" expense. The recent legislation with regard to scientific research extends only to expenditure incurred by a 'trader,' and is inapplicable to a member of a profession.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Attilology*, Westcott London. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required as proof: are not sent abroad. RECENT ADVANCES IN THE PHYSIOLOGY OF VISION—PART II*

BY

H HARTRIDGE, MD, ScD, FRs

Professor of Physiology, St Bartholomew's Hospital Medical College

When Young's three-colour theory was first put forward by its celebrated proposer it dealt adequately with all the facts of colour vision which were known at that time. It stated that all colours, including white, can be matched by suitable mixtures of three spectral primary colours—red, green, and blue. As methods of investigation improved and the scope of the inquiry widened, deficiencies in the theory began to disclose themselves. Thus Sir John Parsons (1924a) wrote "Difficulty is experienced when an attempt is made to explain the phenomenon of peripheral vision, or of induction, by the theory." Recognition of this difficulty did not cause the abandonment of the theory, because it still had much to recommend it, it was easily understood, it provided a useful classification of the various types of colour-blindness, it offered a feasible explanation of many visual phenomena, and it was an incentive to further research. By degrees, however, its position has deteriorated with the acquisition of further knowledge, in which connexion special reference should be made to Granit's work (1943, 1945), in which he applied the micro-electrode technique to the retinae of many mammals. He did not find that there were three types of colour receptor, as would have been expected on the basis of Young's theory—namely, red, green, and blue—but as many as seven in the frog and four in the cat. These researches, which I reviewed last year (Hartridge, 1946a), were a serious setback to Young's theory, which had held the field for more than a century.

Section I Retinal Micro-stimulation

When Granit's researches on animals were published I began to look for a method which would be applicable to an intact man. In the case of an animal the cornea, lens, and vitreous may be removed, and the electrode placed direct on the individual fibres of the optic nerve as they pass across the surface of the retina to leave the eyeball at the optic papilla. In the case of man, except under unusual conditions—where the eyeball has been seriously injured as the result of an accident, or where it is to be removed for medical reasons—Granit's method cannot be applied, and therefore a different principle has to be used. The plan I finally adopted (Hartridge, 1947) was to apply to chosen parts of the retina pencils of white or coloured light which were so narrow that they stimulated small groups of receptors, or even, under good conditions, single receptors. These tenuous beams of light were produced by a lens system of special design which resembled a microscope used the reverse way round. Whereas the latter magnifies, the micro-stimulator lens system diminishes the images of small sources of white, or of monochromatic, lights until they become mere pin-points. Their geometrical images subtend at the eye an angle of 8 seconds of arc, and they form on the retina geometrical images whose diameters are equal to one-fifth of a cone unit.

* The first part was published in the *British Medical Journal* April 27, 1946 p 637.

Before using the instrument care was taken to correct as perfectly as possible defects present in the lens system of the observer's eyes. As a rule only one eye was used at a time. This instrument gave satisfactory results and was employed for studying a number of different problems. Three concern us here: (a) to determine whether there is a constant fixation-point in the fovea for light of any given colour and brightness, or whether different fixation-points are used at different times, (b) to determine whether lights of different colour use the same or different fixation-points, and (c) to ascertain which colours, if any, are to be seen when a tiny ray of white light is caused to explore the surface of the retina.

(a) The position of the fixation-point for green rays (5200 ÅU), was determined in relation to a small scotoma for red rays which existed near the fovea, in my left eye (Hartridge, 1946b). The precise position of the fixation point was measured a number of times, on three different evenings and was found to alter hardly at all in position. The greatest difference between the three mean values was found to be less than one quarter cone unit.

(b) When rays of other colours were similarly tested it was found that each colour had a definite fixation point of its own. In all, seven different points were located—namely for red, orange, yellow, green, blue-green, greenish blue, and blue. The red and the orange fixation points were to the left and below the green ones, the yellow, the green, and the blue-green points were all close to one another, while the greenish blue and the blue points were to the right and below the green ones in the visual field. These positions were confirmed by another method, so far as red, green, and blue were concerned, which involved the estimation of eye movements required in order to fix in turn first one of these coloured points, and then another.

(c) With regard to the third type of experiment it was found that a beam of white light remained white in appearance wherever it was situated on the retina, unless there was also present a conditioning coloured light in the visual field. When this was the case colour changes were found to occur. Thus when the conditioning coloured light was red the white light looked white in certain positions but red and orange in others. Examined in this way the white light was seen on different occasions to have the following subjective colours: red, orange, green, blue-green, greenish blue or blue. Yellow was also seen under advantageous conditions making seven colours in all.

Thus by means of two different methods—the fixation method and the subjective colour method—evidence was found for the presence in the human fovea of several different kinds of receptor. Now, such methods may give fallacious results unless great caution is exercised by the observer in their performance and interpretation. In consequence it would have been unwise to place reliance on them unless they had been confirmed by the other method which are described in the following sections.

Section II Colour Mixture Experiments

With the apparatus available to Thomas Young and his contemporaries it seemed possible to match exactly the monochromatic yellow light of the spectrum by a suit-

able mixture of spectral red and spectral green lights. As spectroscopic apparatus improved, so as to produce purer spectra and to permit more exact comparisons to be made, it was found that a precise match was not obtained, because the monochromatic yellow was always more saturated—that is, contained less white light—than the yellow produced by mixing red and green. Thus for equality to be obtained either white or, better, blue light was mixed with the pure yellow. In the case of the blue-green colours it was red light which was added for the same purpose. In the case of the red or the violet near the ends of the spectrum, it was green light which was required. Now, adding a colour to one side of a match is equivalent to subtracting it from the opposite side. The colour equations therefore took this form

- (a) Extreme red = red + blue – green
- (b) Yellow = red + green – blue
- (c) Blue-green = green + blue – red
- (d) Extreme violet = red + blue – green

These negative amounts of red, green, and blue were accounted for in various ways. Thus Wright (1946a) states 'All it means is that no physical radiation is capable of stimulating one of the receptor systems without causing activity in the other systems.' This may be restated 'A red light stimulates the red receptors, but also to some extent the green ones and the blue ones, and similarly for lights of other colours.' Gothlin (1943) held a different opinion, and thought that cerebral inhibition accounted for these negative values. At present there is no confirmatory evidence for either of these views.

Whatever the cause of the negative values may be there is no doubt that subtracting a given colour is equivalent to the addition of its complementary. Thus the subtraction of red is equivalent to the addition of blue-green, the subtraction of blue equals the addition of yellow, and the subtraction of green equals the addition of both extreme red and extreme violet.

The four equations given above therefore become

- (a) Extreme red = red + blue + extreme red + extreme violet
- (b) Yellow = red + green + yellow
- (c) Blue-green = green + blue + blue-green
- (d) Extreme violet = red + blue + extreme red + extreme violet

On the left-hand side are all the colours of the spectrum, of which red, yellow, blue-green, and violet have been taken as examples. On the right-hand side are the spectral components required to match them. The latter comprise the following colours: extreme red, red, yellow, green, blue-green, blue, and extreme violet, seven colours in all.

Section III Colour-blindness

It used to be thought that there were four kinds of defective colour-vision—red-blindness, green-blindness, blue-blindness, and total colour-blindness—and that the first three were due to the failure of one type of receptor, while the last was caused by a complete breakdown of all three types.

Such a classification fitted in with the three colour theory and lent it very strong support. Soon, as the result of research further varieties of colour deficiency came to light. In addition to the red-blind (protanopic) there were also the red-deficient (protanomalous), in addition to the green-blind (deutanopic) there were the green-deficient (deutanomalous) and so on. Then it was found that there were various grades of failure of vision for the red rays: in some cases it was the red near the end of the spectrum only that was involved, in other cases it was the whole of the red; in still other cases the red and the orange were affected together, and so on. In order to account adequately for all these different grades the red sensation

had to be supposed to consist of several separate parts, each one of which could become deficient by itself or in conjunction with other parts. In the case of green blindness also, changes of mechanism had to be introduced, and the original idea of a partial or a complete deficiency had to be replaced by a different plan altogether proposed by Pitt (1944)—namely, a partial, or a complete, linking of the red receptors with the green ones. So with blue blindness it is no longer regarded as a defect of the blue receptors, as was once the case, but as being due to absorption of blue rays either by some yellow pigment in the crystalline lens or in the retina (Parsons, 1924b). Thus the original simple arrangement, which appeared to support the three-colour theory so strongly, has gone, for not one of the types of colour-blindness is believed to-day to be caused by the absence of a single sensation mediated by a particular type of receptor. Thus Young's original theory can no longer look to colour-blindness for support, as it once could. In order to come into line with the facts of colour-blindness as we now know them, the red receptor has to be regarded, as Wright (1946b) has pointed out, as being a composite affair, consisting of several different types of receptor—some for red rays, some for orange rays, some perhaps for yellow rays—interconnected in some way in order to mediate the red sensation. Hence Young's theory has been forced to adopt polychromatism in order to account for colour-blindness.

Section IV The Inconstancy of the Receptor Curves

In the early days of the colour theories it was usual to deal with sensations. Accordingly, Young's theory supposed that to each primary colour there was a corresponding sensation. Thus red light, incident on an active retina caused under suitable conditions a red sensation to be perceived, and so on for green and blue. Nowadays, in keeping with the times, we prefer to think in terms of the photo-receptors present in the retina, and by carefully planned experiments we try to determine their sensitivity to different parts of the spectrum, this is plotted against wave-length, thus producing what is called a 'response curve'. If the response curves derived by the different methods resembled one another exactly it would be very encouraging to Young's theory. But such is a long way from being the case, so far as present evidence is concerned. The red receptor is particularly unfortunate in this respect, for when deduced from the colour mixture equations it has a smooth curve, rising to a single crest at about 5,800 Å U (Fig 1). When, on the other hand, it was deduced by Willmer and Wright (1945) from the colour mixture curves for the human fovea, when viewing objects at small visual angles, it was found to have two crests—one at about 5,600 Å U and the other at about 6,000 Å U (Fig 2). Further, in persons with green deficiency the crests of the red response curves differ in position, and in subjects with defective green vision they also vary (Figs 3 and 4). When the troughs of the red response curves are similarly considered it is found that they also differ in position in the spectrum according to their derivation. Thus the curve obtained from colour mixture measurements has a trough at 5,000 Å U (Fig 1). That for reduced foveal colour vision has one at 4,600 Å U (Fig 2), while green-blind persons (deuteranopes) have a red response curve that has a trough at 4,400 Å U (Fig 3).

The green response curve is not so variable in shape as the red, but in this case also some differences occur which are hard to explain. The blue response curve has a crest which varies from about 4,500 to 4,800 Å U, but this may be caused by individual peculiarities in macular pigmentation.

Section V Hue Discrimination

When a person with normal colour-vision looks at a spectrum there are parts where there is a rapid change of hue, and other parts in between where the change is slow. Thus it is particularly slow at the extreme red and violet ends of the spectrum and particularly rapid in the yellow. A thorough examination of the spectrum shows that there are four places where discrimination is good, which separate five places where it is poor (Fig 5). Now the three-colour theory can account for only two of the good points and for only three of the poor ones (Fig 6). This is so because good discrimination depends on the overlapping of the sensations, so that one—for example, the red—is diminishing at the same time that its neighbour, the green, is increasing, with change of position in the spectrum. Since

How, then, can a curve be accounted for, consisting of four U's, such as persons with normal vision are found experimentally to possess? It would seem evident that their colour-vision must be mediated by not less than five types of receptor. Some further evidence on this point will be given in the next section.

Section VI Vision of Objects Subtending Small Angles at the Eye

There are several conditions which cause a subject with normal colour-vision to become temporarily colour-deficient or even colour-blind. Three of these conditions will be discussed here—namely, (1) a reduction of visual angle, (2) a reduction of illumination, and (3) the use of peripheral vision. Under all these conditions, with suitable adjustment, colour-vision gradually becomes defective,

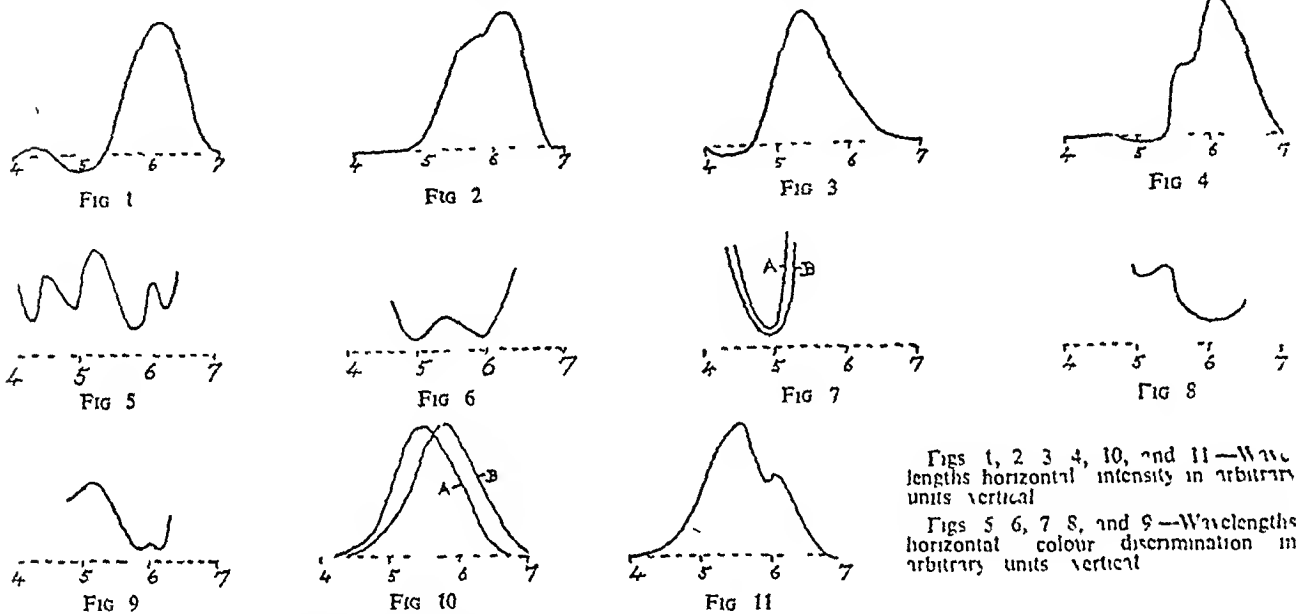

Fig 1—Red response curve for a subject with normal colour vision. Fig 2—Red response curve for reduced foveal colour vision. Fig 3—Red response curve for a green blind (deuteranopic) subject. Fig 4—Red response curve for a green defective (deuteranomalous) subject. Fig 5—Hue discrimination curve for a subject with normal colour vision. Fig 6—Normal hue discrimination curve calculated by Helmholtz, from Young's theory. Fig 7—Hue discrimination curves A for a red blind (protanopic) subject, B for a green blind (deuteranopic) subject. Figs 8 and 9—Hue discrimination curves for reduced foveal colour vision. Fig 10—Luminosity curves A, for a red blind (protanopic) subject, B, for a green blind (deuteranopic) subject. Fig 11—Luminosity curve for reduced foveal colour vision.

there are two such places of overlap, one between the red and green and the other between the green and blue, two regions of good hue discrimination can be accounted for. This was found by calculation, both by Helmholtz and by Judd (Fig 6). These ideas are substantiated by an examination of the hue-discrimination curves either of red-blind or of green-blind subjects, for in both cases the curves are U-shaped (Fig 7), the centre of the trough occurring at the point of the spectrum where the response curves are undergoing the greatest relative change for a given alteration of wave-length. On the contrary, at parts of the spectrum where there is only one response curve present, there is no hue discrimination at all, and the curve in consequence shoots up to very high values. It does this on both sides of the trough, thus causing the curve to have a U shape. Now according to Young's theory of the three fundamental receptor processes, if one type is missing only two remain, thus both red-blind and green-blind persons are called "dichromats". Dichromatism is consequently always associated with a U-shaped hue discrimination curve. Subjects with trichromatic vision would therefore be expected to have a double U-shaped curve, as both Helmholtz and Judd (1932) calculated to be the case

until finally a state of total colour-blindness is attained. In all three cases there appears to be a clearly marked intermediate stage between full colour-vision and complete colour-blindness, at which the subject is partially colour-defective. For this intermediate type of vision I have suggested the name "reduced colour-vision". From what has been stated above it may be inferred that there are three types of this type 1, that produced by a reduction of visual angle, type 2, that produced by a reduction of light intensity, and type 3, that produced by the employment of the periphery of the retina. The first two types appear to have much in common, in fact, it may be found that they are identical in their properties. The third type is entirely different from the other two (see Section VII).

Type 1—When coloured objects which subtend very small angles at the eye are looked at their colours become altered. Blue is replaced by dark grey or black, and yellow by pale grey or white. Other colours are also seen to change. Thus green loses its yellow tint and is replaced by blue-green, crimson is replaced by orange, and purple and mauve alter to shades of brown. Four colours seem to undergo hardly any change at this stage—red, orange, blue-green and greenish blue. White undergoes no perceptible change at all. According to Williams (1944) and to Thomson and Wright (1947) this change is

colour vision is due to a temporary defect in the blue receptors as if the retina had become locally blue blind. If this were the case then on the three colour theory two sensations would be left in action—namely, the red and the green. Therefore white since it stimulates both sensations should look yellow and so the colours seen by the eye should be red, yellow green, and various hues made by their mixture. But the colours seen are red, orange, white, blue green, and greenish blue so that the explanation offered by Willmer and by Thomson and Wright seems to be at variance with the facts. A further piece of evidence against the acceptance of their explanation is the fact that a decrease in the brightness of the spectrum occurs both in the yellow and in the blue when normal colour vision is replaced by reduced colour vision, as is shown by the change in the shape of the luminosity curve obtained by Wright (1943) (see Figs 10 and 11). Now, a decrease in the blue would be expected on their hypothesis, but not a decrease in the yellow as well, so that in this respect also their hypothesis does not seem to fit the observed facts. But there is a further difficulty in accepting their conclusion—namely that if reduced colour vision is equivalent to tritanopia caused by the temporary insensitiveness of the blue receptors then according to Young's theory a form of dichromatism should remain and thus the hue discrimination curve should be of the simple U type as shown in Fig 7. Thomson and Wright (1947) did not obtain such a curve, however, but curves with a more complex form as shown in Figs 8 and 9. This indicates the presence of a more elaborate type of vision than that provided by two receptors only. In my view reduced foveal vision is mediated by at least four receptors—red, orange blue green and greenish blue, then the addition of yellow and blue in order to reconstitute full colour vision should involve six types of receptor at least. Such a supposition is completely at variance with the trichromatic theory.

Type 2—The reduced colour-vision which is found under conditions of feeble illumination was investigated by Abney and Festing (1892). They found that at an illumination of 0.0025 f.c. the spectrum appeared to begin at 6,250 Å in the orange and reached its full intensity at 6,000 Å. From there the colour became progressively paler, with change of wave length, until all colour was lost at about 5,800 Å in the yellow. The spectrum remained colourless to 5,650 Å, where a blue green tint slowly developed to reach its maximum at 5,200 Å. This darkened and ceased to have a noticeable colour at about 5,000 Å in the blue green part of the spectrum. Thus the red and blue ends of the spectrum had been replaced by dark grey or black, and yellow had been replaced by pale grey or white as is found to be the case with the reduced colour vision (type 1) caused by a reduction of visual angle. I have found that for every light intensity from 3,000 to 0.01 f.c. there is a corresponding visual angle at which full colour vision is replaced by reduced colour-vision.

Type 3 will be considered in the following section.

Section VII The Colour-vision of the Periphery of the Human Retina

If coloured test objects be examined first by the fovea centralis and then by a more peripheral part of the retina it will be found that certain of them undergo changes of colour or brightness. The colour-changes are summarized in the Table, together with those for reduced foveal colour-vision produced by a decrease in visual angle which were considered in the previous section.

Table showing Colours Seen by Peripheral and by Reduced Foveal Vision

Colour	Periphery	Reduced Visual Angle
Red	Dark yellow brown	Red
Orange	Yellow brown	Orange
Yellow	Yellow	Pale grey
Green	Yellowish grey	Pale blue green
Blue green	Grey	Blue green
Violet	Dark blue	Black
Purple	Dark blue grey	Dark red brown
Mauve	Dark yellow brown	Red brown
Crimson	Yellow brown	Orange
White	White	White

These changes may be contrasted as follows with a reduction of visual angle the yellow and the blue drop out, leaving red-orange and blue-green, with peripheral vision, on the contrary, it is the red orange and the blue green which drop out and yellow and blue which remain. Thus they appear to be the antithesis of one another. During both changes it should be noticed that white continues to be seen as white, indicating in my opinion, that in both cases the colours which fall out are complementary pairs, leaving complementary pairs behind. Thus if the retina contained three pairs of complementary receptors—red and its complementary blue green, orange and its complementary greenish-blue, and yellow and its complementary blue—and if these dropped out in pairs it would fit in with several of the observed facts. This does not exclude the possibility that, in addition to the complementary pairs just mentioned, there are other receptors which function in normal vision.

Section VIII The Rival Theories

Only when the colour properties of peripheral vision remained apparently unaccounted for by Young's theory was there the possibility that one day the problem would be satisfactorily cleared up. But now that this theory is out of line with modern work on foveal vision, hue discrimination, micro stimulation, micro electrode results, and even colour-mixture and colour-blindness, the confidence of even its strongest supporters is shaken, and they give consideration to other theories of colour-vision.

Colour-mixture and micro stimulation both suggest seven receptors, hue discrimination, more than five, reduced foveal vision, six or more. So that some form of polychromatic theory would seem to be indicated. If that proves to be the case a question that will arise is this: Why has vision been thought to be trichromatic for so long—in fact, until the recent introduction of more critical methods of research? One possible explanation may be founded on Granit's observations on frogs, for he discovered three main groups of receptors—a red group with crests at 6,000 and 5,800 Å, a green group with crests at 5,400, 5,200, and 5,000 Å, and a blue group with crests at 4,600 and 4,400 Å. Now, it is possible that these act in group formation not because their nerve fibres are interconnected to form three main sensations but because of the overlapping of their response curves. Thus one touch-spot may behave as a single unit neither because it contains only one touch-sense organ nor because the nerve fibres of all the touch-sense organs present are interconnected, but because a force applied to the skin almost always stimulates them at the same time.

Wiltshire has now adopted a scheme for part time nursing similar to that working successfully in Gloucestershire, and it is hoped to recruit volunteers particularly from outlying districts by the provision of adequate transport to and from work.

ON COMPLETE REMOVAL OF THE PROSTATE

A PRELIMINARY COMMUNICATION

BY

H S SOUTTAR, CBE, MCh, FRCS

It will be generally agreed that the extravesical approach to the prostate introduced by Millan presents considerable advantages over the older transvesical methods. It enables one to observe every step of the operation in a way which was formerly impossible, bleeding is readily controlled, and the post-operative period is short and easy. Some recent experiences have, however, suggested to me that the operation for prostatic obstruction performed by this route is still capable of substantial development, and although some considerable time must elapse before this can be established it seemed worth while to place these experiences on record.

History of a Case

In operating a short time ago upon a man of 75 with obstruction of some standing I was surprised to find that instead of enucleating an adenoma as I intended I was enucleating the entire prostate, which had become detached from the triangular ligament. Moreover, on drawing the prostate away from the triangular ligament a tube of urethra emerged from that structure as a substantial muscular cylinder four centimetres in length. The only course was to divide this tube close to the prostate which was then easily excised from the neck of the bladder after division of the ejaculatory ducts. The urethra was sutured to the neck of the bladder, and the latter was then sutured firmly to the triangular ligament, completely obliterating the prostatic cavity. To my great relief the operation was a complete success, the patient a rather feeble old man, passing water normally on the sixth day.

Anatomy of the Prostate

On discussing the case with Prof. Wood Jones he told me that the free urethral tube is a fact of normal anatomy, although it was quite new to me, and I know of no reference to it in any textbook. What was abnormal in my patient was the ease with which the prostate became detached. I have since carried out a number of dissections which fully confirm this view. The normal anatomy is as follows:

The prostate is attached to the back of the pubes by two dense

FIG 1—Normal anatomy

FIG 2—Ligaments divided, prostate retracted

FIG 3—Urethra divided, prostate excised

FIG 4—Urethra sutured to bladder

FIG 5—Bladder sutured to urogenital diaphragm

bands of great strength—the pubo-prostatic ligaments. Each of these forms a rounded tendon three or four millimetres in diameter, separated by a deep recess, the cave of Retzius, into which emerges the dorsal vein of the penis. On dividing these ligaments the prostate is easily shelled out from its bed, which is formed in front by the levator prostatae muscles and further back by the dense fascia of Denonvilliers, which separates the prostate from the rectum. As the prostate is drawn upwards the membranous urethra emerges from the compressor muscles of the triangular ligament as a muscular tube three to four centimetres in length. It is true that a venous plexus is opened up, as this surrounds the prostate, but it does not appear to be of great moment and bleeding from it is easily controlled.

The existence of this urethral tube is obviously of great importance, for it enables us to provide a complete epithelial lining after removal of the prostatic urethra, and would seem to avoid any risk of stricture. It is of course a fragile tube and requires careful handling, but it is substantial enough to allow of accurate suture into the neck of the bladder. It is convenient to proceed as follows:

Operative Procedure

A No 12 rubber bougie is passed into the urethra as far as the prostate or into the bladder. The prostate is exposed by a suprapubic incision and drawn upwards so that the pubo-prostatic ligaments are clearly seen. These ligaments are now divided, the bougie providing a guide to protect the urethra, when on drawing the prostate upwards the urethra will emerge from the triangular ligament carrying the bougie. The prostate can now be shelled out from its bed without difficulty, the bougie is withdrawn from it, but remains in the urethra which is divided at the apex of the prostate. The prostate is turned forward and detached from the bladder after dividing the ejaculatory ducts. The bougie supporting the urethra is passed into the bladder and out through a puncture in its wall. The urethra is sutured with fine catgut to the neck of the bladder, which is now securely sutured to the triangular ligament, obliterating the prostatic cavity. The

bougie is withdrawn through the bladder so far that it remains as a support for the new junction between the bladder and the urethra. The bladder is drained by a suitable suprapubic tube into which the end of the

bougie may conveniently be fixed. The bougie may be removed in four days and the suprapubic tube as soon as it is certain that the patient can pass water.

FIG 7—Ligaments divided, prostate retracted

Comment

The operation described is of course only a development of the brilliant operation devised by Millan, but it may be a development with considerable possibilities. If further experience confirms its practicability it would seem to present certain definite advantages. The prostate is removed as a whole and the technique of its removal is little affected by its precise pathology. Indeed, it might well be applicable to early carcinoma. The cavity left is completely obliterated and later haemorrhage is unlikely. A complete urethra is provided from the outset and the risk of a stricture is minimized. So far the operation has been carried out in only a few cases, and obviously a wide experience will be required before its value can be assessed. But it would seem to be based on sound anatomical principles and sufficient success has already been achieved to convince me that it is worthy of an extended trial.

The following recommendations on visual standards for candidates for the teaching profession have been made by the Faculty of Ophthalmologists at the request of the Ministry of Education: (1) Visual acuity with correcting glasses should not be less than 6/12 in the better eye. (2) At the age of 18 no refractive error should debar a candidate from training, but all cases in which the vision in either eye is less than 6/9 uncorrected must be referred for an ophthalmic surgeon's report and prognosis. (3) On reference to an ophthalmic surgeon information is required on the following points: (a) The nature and extent of the defect. (b) whether it can be corrected by glasses satisfactorily for the project in view. (c) whether it is progressive. (d) whether the existence of the defect is likely to interfere with the candidate's efficiency as a teacher.

A NEW EUPHORANT FOR DEPRESSIVE MENTAL STATES

BY

G TAYLEUR STOCKINGS, MB, BS, DPM
*Late Major, Specialist in Psychological Medicine R.A.M.C.
Ernest Hart Memorial Scholar British Medical Association*

The Syndrome of Thalamic Dysfunction

The syndrome of thalamic dysfunction, or neurotic depression, is the commonest of psychiatric conditions encountered in general practice, and often one of the most intractable and difficult to treat effectively. The commonest forms of the condition are the chronic neurotic depressions, anxiety states, reactive and hysterical depressions and obsessional disorders. The milder forms of depressions of later life, in which the dysphoria is unaccompanied by hallucinosis, delusions, and other gross psychotic symptoms, may also be included in this group of conditions.

The essential feature common to all of these disorders is a condition of the nervous system in which the perception-threshold for unpleasant affects and sensory impressions is markedly lowered, while that for pleasant affect and sensation is correspondingly raised—the anhedonic or dysphoric syndrome. The resulting dysphoria or mental pain may present itself in one or two forms, or a combination of both. In the manifest type it takes the form of conscious depression or unpleasant mental tension. In the sensorial or conversion type it presents itself as a persistent and disagreeable bodily sensation either localized or diffuse, common examples of which are pressure-headache, generalized pains, hyperalgesia, gastric pains without organic basis, vertigo, and feelings of abnormal tiredness and weakness.

Although it is generally taught at the present day that these conditions are entirely psychogenic in origin, there would appear to be strong evidence that the basis of the condition is primarily a disturbance of the thalamic hypothalamic mechanisms, possibly a metabolic disorder. Suggestive facts are the absence in a large proportion of such cases of any evidence of mental conflict, and the concomitant symptoms of disturbed body-metabolism and autonomic imbalance, such as vasomotor disturbances, central nervous instability as shown by muscular tremors, hyperalgesia, and other sensory disorders, vegetative disturbances, and metabolic anomalies as demonstrated by biochemical tests.

The commonest symptoms of thalamic dysfunction in order of frequency are depression, irritability and emotional instability, with anxiety and sense of unpleasant mental tension, in the affective sphere, in the sensory sphere, pains and paraesthesias of various kinds, such as pressure headache, various vague pains and aches of infinite variety which may be referred to any part of the body, gastralgia, low backache, and dysuria or other symptoms referred to the urogenital tract, in the sphere of thought, inability to concentrate, obsessional thoughts, phobias, and transient periods of confusion ("black-outs"), in the motor system, tremors, sensations of weakness and loss of energy, with abnormal tiredness, and in the vegetative systems, insomnia, anorexia, gastrointestinal disturbances, vertigo, sexual dysfunctions, and vasomotor symptoms such as flushing, palpitations, effort syndrome, and syncopal attacks without apparent organic basis.

The thalamic dysfunction state may be regarded as a response of the organism to stresses of various kinds. It is one of the commonest causes of chronic ill-health and

loss of efficiency, and one of the most unsatisfactory of conditions to treat. Its victims form a large proportion of the "chronics" who regularly attend hospital out-patient clinics, and there is probably no patient who is more dreaded by the overworked practitioner than the chronic neurotic-depressive.

Treatment of the thalamic dysfunction syndrome is often unsatisfactory because there is no specific drug therapy known at present for the condition. Psychotherapeutic methods are lengthy, tedious, and often unsatisfactory, since in a large proportion of such cases the causal factors (unsatisfactory home life, faulty conditioning in childhood, etc.) cannot be removed, while not uncommonly it is found that the neurotic behaviour-patterns persist even when the precipitating stresses have been removed. Psychotherapeutic methods usually require specialized training in the physician, and an effective symptomatic therapy aimed at keeping the patient fit and in full working efficiency during the period of analytic or other treatment is at present lacking, since the commonly employed remedies, such as cortical sedatives and stimulants, offer at best only partial relief on account of their lack of specific effect on the thalamic centres, while endocrine preparations, vitamins, and measures to improve the general health have, generally speaking, proved largely unsuccessful.

Principles of Treatment by Euphorogenic Drugs

The most important therapeutic advances in psychiatry, as in general medicine, have been the discovery of specific pharmacological or physical agents for the various disease conditions. Similarly, the logical answer to the thalamic dysfunction states would be a drug possessing a specific reversing effect on the thalamic disturbance—in other words, a powerful euphorogenic drug which would be therapeutically effective and at the same time free from the objectionable properties usually associated with narcotic compounds.

The ideal euphoriant for clinical use should possess the following properties. It must induce a high degree of euphoria, must be stable and fully active by the oral route, be reasonably rapid-acting, and have a prolonged action. It must be of low toxicity, non-cumulative, and free from after-effects and undesirable effects on the higher cortical functions, such as impairment of concentration, judgment, and memory. Most important of all, it must not have the property of inducing the condition of addiction or physical dependence when administered for long periods.

The last-mentioned point is of especial importance, since there is a common and widespread belief that all euphoriant drugs are necessarily habit-forming, whereas this is in fact not the case. The true addiction syndrome (physical craving, tolerance, abstinence syndrome, and personality deterioration) is peculiar to the drugs of the ecgonine (or cocaine) and phenanthrene (or morphine) groups, whereas mescaline and cannabis indica, the two most powerful euphorants known, do not induce a comparable addiction. The addiction-forming property would therefore appear to depend on chemical constitution rather than degree of euphorogenicity, since the two compounds just mentioned are chemically unrelated to the cocaine and morphine drugs. Theoretically, therefore, the addiction problem should not offer an insuperable obstacle to such a form of therapy, provided the compound employed is not one of the ecgonine or phenanthrene class.

Up to the present time no drug which fulfils these requirements has been known to medicine. During the last century attempts were made to utilize the euphorogenic properties of cannabis in the treatment of depressive states, but these were found to be unsatisfactory for various reasons: chief of these were the difficulty of obtaining

reliable and stable preparations of this drug, its uncertain action, and its peculiar and undesirable side-effects, of which actual intensification of the dysphoria is one of the commonest. The discovery of the new synthetic cannabis-like derivatives of the dibenzopyran class within the last few years, however, has placed in our hands an entirely new type of euphoriant drug with properties which render it an extremely promising therapeutic agent in psychiatry.

The Synthetic Tetrahydrocannabinols

These compounds have been produced as the result of the work carried out by Adams and his colleagues in America and of Todd and his colleagues and the Roche Research Department in this country.

Several compounds of this type are known, and one of the most active pharmacologically is the synthetic hexyl analogue called in America synhexyl, pyrahexyl, or parahexyl. Chemically it is 1-hydroxy-3-*n*-hexyl-6-6-9-trimethyl-7-8-9-10-tetrahydro-6-dibenzopyran, and has the following structural formula:

It is synthesized by condensation of ethyl-5-methylcyclohexanone-carboxylate-2 with 3-5-dihydro-*n*-hexylbenzene, followed by treatment of the condensation product with methyl magnesium iodide. It is a pale-yellow, translucent, very viscous, odourless resin, soluble in organic solvents but insoluble in water, alkalis, and acids. The synthetic lower homologue in which *n*-amyl replaces the *n*-hexyl radicle is pharmacologically less active. Its laevorotatory form is several times as active as the dextrorotatory form.

Pharmacology of Synhexyl in Man

The pharmacological properties of synhexyl are in many respects similar to those of cannabis, but there are several important qualitative differences in the human subject. The following data were obtained as the result of a series of experiments which I carried out on myself, a group of normal subjects, and a group of 50 depressive patients. My findings confirm that the drug is a powerful euphoriant with a specific action on the higher centres, particularly the thalamic system and its cortical connexions. Synhexyl is rather more potent weight for weight than natural cannabis, the effective dosage being from 5-15 mg in normal subjects to 60-90 mg in depressive patients. In narcotic drug addicts doses of 60-240 mg three times daily may be given without ill effects (Himmelsbach). On account of its resinous nature the drug is most active when administered by the oral route, and the preparation I used was in the form of a powder made by absorbing the drug on silicic acid and contained in gelatin capsules or as compressed tablets after absorption on kieselguhr.

The general effects in normal man are as follows. There is first a latent period of 1½ to 3 hours before any effect is felt, this being about twice the latent period for the same dose of cannabis extract. The onset of the synhexyl effect is characteristically abrupt, with a sudden and peculiar sensation of lightness and mild intoxication accompanied by acceleration of the pulse and feelings of slight palpitation and oppression in the head and chest. Transient feelings of anxiety and vertigo may occur at the onset, but these usually pass off in the course of a few minutes to half an hour. The euphoric effect quickly

follows and consists of a pleasant feeling of happiness and exhilaration with a marked sense of physical well-being and self-confidence; there is a sense of relief from tension and anxiety, and the threshold for unpleasant affect is markedly raised, while that for pleasant feeling-tone is correspondingly lowered. There is increased enjoyment of normally pleasant impressions, and zest for life and working capacity may be actually increased in the early stages of the intoxication. Later this effect gives way to a sense of dreamy apathy and contentment, which with the larger dosages may reach the stage of ecstasy. There is often increased speed of the stream of thought, with a marked increase in the power of fantasy and vividness of visual imagery. With the larger dosages there may in the early stages be a tendency to flight of ideas and pressure of activity. In the sensory sphere there is little or no true analgesic effect of the opiate type. With the higher doses there may be some degree of blunting of sensation, but the senses of taste and hearing may actually become more acute. A generalized sensation of pleasant warmth diffused throughout the body is characteristic.

Hallucinatory phenomena and distortion of the tempero-spatial perception sense of cannabis-mescaline type are not found, although elementary visual sensations in the form of photopsias and simple coloured patterns may occur when the eyes are closed or the subject is in darkness. A peculiar visual illusion is sometimes seen in which the colours and outlines of objects appear abnormally vivid and a soft golden radiance seems to be diffused over the whole room. With larger doses visual illusions of cannabis type may be experienced in which simple patterns appear to acquire complex and fantastic forms, the whole effect being extremely pleasing to the subject. On the motor side there may be slight restlessness in the early stages, similar to what is found with moderate doses of benzadrine. Hyperreflexia is common but ataxia and motor incoordination are seen only with the largest doses. Kata-tonia and rigidity as seen with mescaline are never found.

The vegetative effects are very slight, consisting of moderate tachycardia in the early stages, slight mydriasis, and dryness of the mouth. Appetite is usually increased, there is no respiratory or peristaltic depression, and sleep following the intoxication is normal and dreamless. Slight drowsiness may occur in the later stages, but "hangover" effects are seen only after very large doses.

Characteristic of the synhexyl effect is intermittency, the symptoms, as with cannabis and mescaline intoxication, occur in rhythmic waves with intervening periods of apparent normality. The average duration of the effects is from 8 to 10 hours from the time of onset of the symptoms.

With excessively large doses, the toxic effects are frightening rather than actually dangerous, resembling those of acute cannabis poisoning. The onset occurs with a sudden feeling of acute apprehension and collapse, with rapid bounding pulse, mydriasis and dryness of the mouth and throat, hyperreflexia, clonic twitchings, mental confusion, headache, and vertigo. Euphoria is absent, the emotional reaction being one of acute anxiety and apprehension. These symptoms usually pass off completely in 12 to 24 hours. The biochemical changes produced by the drug are slight, consisting of increased blood concentration and haemoglobin value, and mild hypoglycaemia. There may be slight diuresis and rise of temperature, other changes include a slight rise in blood pressure, cerebral hyperaemia, and increase in the venous pressures.

Absorption of the drug apparently takes place through the lacteal vessels of the small intestine, since it is a resinous substance and cannot therefore be absorbed direct through the stomach wall, as is the case with alkaloids and other water-soluble substances. This would account

for the long latent period between ingestion and onset of symptoms of intoxication, which is normally of the order of two to three hours. The drug is partly destroyed by oxidation in the liver, but a certain proportion is excreted unchanged in the urine, in which respect it resembles natural cannabis and mescaline.

Effects on the Intellectual Functions

Studies which I made on myself and a group of normal subjects show that with ordinary therapeutic doses there is little or no deleterious effect on the intellectual performance. Seven of my depressive patients were studied by means of psychometric tests selected from the revised Terman-Merrill scale. The results suggest that memory work calling for the use of reasoning powers and logical integration of facts suffers slightly after taking the drug, but that the more mechanical memory is unimpaired and may actually show a slight improvement. In normal subjects engaged in work of an intellectual nature there appears to be little or no falling off of intellectual capacity, the only inconvenience experienced from the drug being the slight distractibility and pressure of ideas, and the tendency to day-dreaming and wandering of the stream of thought in the later stages.

Therapeutic Trials in Depressive Patients

Therapeutic trials were made with the drug in a series of 50 patients showing the thalamic dysfunction syndrome, including cases of both the dysoxic (depressive-psychotic) and the neurotic-depressive types. The dosages employed varied from 15 to 90 mg, the drug being administered in all cases immediately on rising in the morning before a meal was taken. Suggestion and other psychological factors which might have vitiated the results were eliminated by substituting, without the patient's knowledge on certain days, inert control tablets of exactly similar appearance to those containing the synhexyl.

The general effects were found to be qualitatively similar to those in the normal subject, except that a considerably higher average dose was required to produce improvement of the depressive symptoms. It was found that the dysphoria itself was ameliorated to a much greater degree than the other symptoms (obsessional thoughts, pains, paraes-thesias, etc.), these features, although themselves little affected, were rendered less distressing and obtrusive to the patient by the action of the drug.

Of the 50 cases tested 36 showed a definite improvement in affective reaction, while 14 were unaffected or made worse. Twenty-seven of the series were neurotic depressives, 20 of whom showed improvement, of these 27, 12 were typical chronic mental hospital cases, of whom 9 benefited from the drug. Of these 12, 9 had previously been treated with electro-anoxia with no improvement, and 3 had been subjected to prefrontal leucotomy with no response. The remaining 23 patients were cases of dysoxic depression, of whom all but 4 were chronic institutionalized patients with mild symptoms of dysphoric type. Four of the 23 had previously received electro-anoxia with temporary improvement only, of these four two responded favourably to the drug.

Of the whole series 16 patients showed associated organic diseases, as follows: gross bony deformity, 2; pulmonary tuberculosis, 2; cardiovascular disease, 5; senile changes, 4; malignant disease, 1; organic nervous disease, 1; thyrotoxicosis, 1. No untoward side effect from the synhexyl was noted in any of these cases. Untoward effects were noted in 5 of the neurotic depressive cases, these included tachycardia, slight dizziness, loss of concentration, drowsiness, and mild degrees of impairment of the intellectual performance.

The criteria for a positive response were taken as the 'following amelioration of mood, as shown subjectively by the patients' own statements and objectively by clinical evidence of diminution of retardation, anxiety, and inward preoccupation, increased zest for and interest in work and occupation, and increased psychotherapeutic rapport. The effect of the drug on obsessional and depressive ideas and pains and paraesthesias of central origin was also noted. The nursing staff were carefully instructed to note during the tests any changes in the general behaviour and demeanour of the patients while receiving the drug. The results with synhexyl were then compared with the response to inert control tablets.

Of the dysoxic patients those in the chronic stationary phase of their disease made the best response. Three dysoxics in the acute depressive phase either showed no response or were actually made worse when synhexyl was given in doses of 60-90 mg.

Of the neurotic group, the quiet apathetic type with depression and general asthenia appeared to do best, this type required the smallest dosage to effect improvement—15 mg. The tense and over-anxious type also showed a good response but tended to require a rather higher dosage—30-60 mg. The anxiety cases with multiple pains and paraesthesias were found to improve considerably as regards the dysphoria, but the drug seemed to have little effect on the actual sensory features. Six of the neurotic cases were severe examples of the obsessive-ruminative type, only one of whom failed to improve with the drug.

Neurotic depressive cases showing a negative response included psychopathic personality with dysphoric features (two cases) and acute hysterical grief reaction with pseudo-hallucinosis (one case).

Illustrative Cases

Case 1—A woman aged 60, with a history of recurrent attacks of depression over the last three years. On examination she was tense, agitated, acutely apprehensive, restless and excitable at times, and expressed self-depreciatory ideas of being wicked and worthless. Orientation and memory were unaffected and insight and judgment were moderately good, but she co-operated poorly in examination owing to her constant preoccupation with delusions of unworthiness. Physical findings were negative. She received electric convulsion treatment with no real improvement, remaining in the agitated state described above. After receiving 30 to 45 mg of synhexyl daily she showed marked improvement, she said she felt brighter, and the agitation and tension were definitely diminished. Although the ideas of unworthiness persisted in mild degree these were much less obtrusive and distressing. No untoward symptoms were noted, and response to control tablets was negative.

Case 2—A man aged 65. The history was very incomplete, but it appeared that he was originally admitted in 1938, following the sudden onset of an acute depressive-confusional state with paranoid and possibly hallucinatory features. On examination he was depressed, apathetic, hypochondriacal and full of ideas of visceral dysfunction, totally lacking in initiative, but well behaved and clean in habits. There were no signs of hallucinosis or paranoid features, but he showed a mild degree of personality deterioration, being at times facile rambling, and irrelevant in conversation. Physical investigations were negative. He responded fairly well to 30 mg of synhexyl daily, becoming brighter, less querulous and preoccupied with his aches and pains, and stated that he felt more cheerful and energetic. The symptoms of cortical deterioration and institutionalization were however, unchanged. No side effects were apparent during the period of medication.

Case 3—A woman aged 67 with a history of recurrent depressive attacks since 1936, and two previous admissions to hospital for acute depression. Examination showed her to be depressed, solitary and lacking in interest and initiative. She complained of obstinate insomnia, and required constant nocturnal sedation. She displayed no evidence of delusions and

hallucinations, but tended to be mildly retarded and sat about aimlessly all day in the ward. Physical examination revealed a slow growing breast carcinoma, for which operation had been considered inadvisable. She had previously received ECT with little or no improvement. She received synhexyl in a dosage of 15 mg daily with considerable subjective and objective improvement. She felt brighter, more alert and cheerful, and showed increased initiative and spontaneous activity. Side-effects were absent, and administration of control tablets failed to reproduce the synhexyl effect.

Case 4—A woman aged 45. She had a history of the onset, three months previously, of acute depression with agitation, ideas of bodily disease, and delusions of sin and unworthiness apparently precipitated by an unhappy home environment. When she was first seen the acute phase of the illness had subsided and she talked rationally, showing considerable insight. She complained of mild depression, fatigability, and insomnia with a variety of vague stomach pains and soreness and pains in her throat. She insisted that she had "swollen and painful glands" in her neck, but examination showed only a small palpable cervical gland on the right side, the throat and tonsils being normal. She also complained of feelings of "being all trembly inside." Delusions of unworthiness were not in evidence. She was a small, pale, anxious-looking woman, but no signs of organic disease were present. She was described by the nursing staff as depressed, solitary, and apathetic in habits. The administration of 45 mg of synhexyl produced an immediate effect, she stated that she felt subjectively brighter and more cheerful, showed increased interest, and her hypochondriacal ideas receded into the background. Vasomotor side-effects were absent, control tests giving a negative result.

Case 5—A woman aged 52, with thalamic dysfunction of conversion hysteria type. She had a history of depression for 18 months following evacuation during the flying-bomb raids and an accident to her son. She had also had a previous depressive attack 28 years ago. On examination she was depressed, tense, emotional, and anxious. Her main complaints were of insomnia, inability to face up to her household duties and a persistent neuralgic pain located under the left breast. Physical findings were completely negative. A few weeks previously she received seven applications of ECT with slight improvement but speedy relapse. The response to 30 mg of synhexyl was immediate, she lost her anxiety and depression said she felt much brighter, and the thoracic pain became much less insistent and distressing although not completely abolished. Control tablets and bromide in full dosage failed to reproduce these effects. No side-effects from the synhexyl were complained of during the period of administration.

Case 6—A woman aged 32 with thalamic dysfunction of anxiety type. She had a history of anxiety symptoms 18 months previously and partial remission but recurrence four months before admission, at which time she had gone to live with and look after her invalid mother. On examination she was a superior and intelligent type of woman outwardly cheerful in manner, but actually tense, anxious, and mildly depressed. She complained of insomnia, intermittent panic sensations with palpitation, and acute feelings of inner tension and "shivering sensations," and loss of concentration. Physical findings were negative, and no signs suggestive of thyroid hyperfunction were evident. The symptoms failed to respond to bromide therapy and psychotherapy. She responded well to synhexyl in doses of 30 mg daily, the anxiety attacks and dysphoria being completely abolished. She stated that she felt much brighter, more confident, and was no longer apprehensive of the anxiety attacks. Her symptoms recurred on changing over to control tablets or discontinuing the synhexyl.

Of these six cases, selected at random from my series, the first four were dysoxic (psychotic-depressive) cases and the last two examples of simple thalamic dysfunction (neurotic depression). The four dysoxic cases were all patients who had passed through the acute phase of their illness and who presented as the principal symptom a residual dysphoria of chronic and intractable type. Of these four, one (Case 2) showed some degree of personality deterioration. The two neurotic cases were of recent onset and in the early stages of their illness. Of the six

cases, three (Cases 1, 3, 5) had previously failed to respond satisfactorily to ECT. It will be evident from this series that synhexyl is as effective in the milder forms of dysoulia as in the purely neurotic-depressive states.

As regards the mechanism of improvement, it should be pointed out that synhexyl does not effect a permanent 'cure' in the same way as electro-anoxia does in typical dysoulia depressions. The effect lasts only during the period of administration of the drug, it is therefore a substitution therapy, like insulin treatment in diabetes or liver extract in pernicious anaemia. The action would seem to be a combination of stimulation and depression, resulting in a general raising of the anhedonic threshold. The principal site of action of the drug is almost certainly the thalamic centres and their cortical connexions, as is the case with morphine and other powerful central analgesic drugs.

The beneficial effects of synhexyl do not appear to be adversely affected by chronicity, concomitant organic disease or the presence of an organic brain lesion, whether pathologically or surgically induced. There is evidence, however, that drugs of this class are ineffective in the acute dysoulia depressions, and cannot be regarded as substitutes for anoxic therapy in this form of metabolic brain disease.

General Conclusions

The results of these preliminary trials would suggest that we have in this class of compounds a promising therapeutic agent for the treatment of the chronic and intractable depressive states. Synhexyl, the most active of this class, has the advantages of low toxicity, minimum of side-effects, ease of administration, and chemical stability. Its use is not contraindicated by the presence of coexisting organic disease, and it is suitable for out-patient practice. Its use does not interfere with other therapeutic measures, such as occupational therapy and psychotherapy. It is free from the risks and disadvantages of the more drastic forms of treatment, and might replace those methods for the milder depressions of later life where for any reason the more drastic procedures are contraindicated.

Its main drawbacks at present are its insoluble nature, slow and uncertain action, and comparatively weak analgesic effect, so that it is relatively ineffective in the severer forms of sensory thalamic dysfunction syndrome. Experiments are at present in progress with the object of producing a water-soluble form with a higher degree of analgesic activity.

Summary

The syndrome of thalamic dysfunction and the principles of its treatment with euphoric drugs are described.

The properties and pharmacology of synhexyl, a new drug of the synthetic tetrahydrocannabinol class, are examined.

The results of therapeutic trials with the drug in a series of 50 depressive patients are given.

My acknowledgments are due to the following: The Research Department of Roche Products Ltd and Dr W S Maclay, of the Board of Control for kindly providing supplies of synhexyl, Dr W A Bain of Leeds University for kindly making up the material for administration, Prof A R Todd, of Cambridge University, for kindly supplying purified cannabis extracts for clinical trial, and Mrs E Bathurst, psychologist, Warlingham Park Hospital for kindly undertaking psychometric tests on the patients tested with the drug.

TYPE I TRIPLE CARDIAC RHYTHM IN NORMAL HEARTS

A STUDY OF 1,360 NAVAL RECRUITS AND PERSONNEL

BY

P J O'MEARA, MB, ChB

Surgeon Lieutenant Commander R N

Triple cardiac rhythm is defined by Evans (1943) as "the cadence produced when three sounds recur in successive cardiac cycles". He then classifies such rhythm into types I, II, and III, which correspond respectively to the proto-diastolic, presystolic, and systolic forms of 'gallop' rhythm of Potain (1856-1900). The term "gallop" is not used in Evans's classification because it is usually only when tachycardia is also present that a cadence somewhat inadequately described as resembling the gallop or canter of a horse is found to be present.

Type I triple rhythm results from the presence of a third heart sound occurring shortly after the normal second. Thayer (1908, 1909) called attention to the fact that the third heart sound, described by Gibson (1907), Hirschfelder (1907), and Einthoven (1907), and mentioned even earlier by Obrastzow (1905), could often be heard in healthy people; he found it in 65% of 231 consecutive individuals below the age of 40. Subsequently Gallavardin (1912) said that he heard it occasionally in young individuals. Bridgman (1915) reported it in 13 out of 16 normal boys aged 12 to 15 and found it in phonocardiograms of all Obrastzow and Gubergitz (1919) heard the sound in 90 to 93% of normal men. Steinberg (1925) in 95% of boys between the ages of 4 and 14, and Melik-Gulnasarian (1932) in 57% of his cases, especially in young men between 20 and 25 years of age. Bramwell (1943) encountered it in 18.8% of 835 recruits referred to him by medical boards of the Ministry of Labour and National Service. Among the 228 individuals in this group below 20 years of age it was present in 43%. None of these recruits had a cardiac lesion.

The purpose of the present purely clinical investigation is to emphasize the frequency of type I triple rhythm in healthy males and to study its features. That its common incidence is not appreciated enough nor its features sufficiently well known is evident from the number of times it gives rise to a diagnosis of mitral stenosis—especially when accompanied, as it may well be, by a mitral systolic murmur and perhaps a split second sound in the pulmonary area. A history of rheumatic fever in such an individual is then accepted as the final link in the diagnosis. As Evans (1943) remarks, "A general acceptance of the fact that this form of triple rhythm is so common in young subjects is overdue." That it is far from rare in the not-so-young requires emphasis also.

Method and Material

The subjects of this survey consisted at first of 1,000 consecutive healthy male adults between 17 and 30 years of age inclusive who underwent routine examination by me for a variety of purposes. Later 360 men above the age of 30 were examined. All these individuals were considered healthy on the grounds that they presented no symptom or physical signs of any disease whatsoever, nor did they give any history of any cardiovascular disease. Some of the older men showed palpable thickening of the radial arteries commensurate with their age, but any who had blood pressures above 160 systolic or 90 diastolic were excluded.

The following routine was adopted in the examination of the heart in every one of these subjects: examination (i) in the erect position, (ii) in the recumbent position, (iii) lying on the left side (left lateral position), and (iv) in the left lateral position after sitting up quickly from the recumbent position six times. Before proceeding to stage three—that is, with the subject on his back—the pulse rate and blood pressure were recorded. In the few cases in which time permitted the performance of exercise tolerance tests, or in which these were compulsory, as in Fleet Air Arm candidates, the information so obtained gave the impression of bearing no significant relation to the occurrence of triple rhythm.

Only those examples of type I triple rhythm were recorded which were evident with the subject erect or lying down, since the examination of the heart does not usually go beyond this stage unless the doctor has some reason to proceed further before eliminating the possibility of a cardiac lesion.

Incidence of a Third Heart Sound

Table I shows the frequency with which a third sound was recorded among 1,360 Naval recruits and personnel.

TABLE I—Incidence of a Third Heart Sound Among 1360 Healthy Males

Age	17-20 incl	21-30	31-40	41-50	51-60	61-67	Total
No. examined	745	255	174	103	70	13	1360
No. with third sound	399	89	44	16	4	0	552
%	53.6	34.9	25.3	15.5	5.7	0	40.6

As already described, the examination of the 1,000 aged 17 to 30 inclusive was completed before that of the older group was begun. Now, although I had been impressed by the frequency of a third sound before beginning the present investigation, it was found that by listening intently for it in case after case the sensitivity of the ear was increased to a remarkable degree; this may be seen from a study of Table II, which gives the incidence of the sound among the last 400 of the 1,000 males under 31 years of age.

TABLE II—The Third Sound in the Last 400 Males Below 31 Years of Age

Age	17-20	21-30	Total
No. examined	325	75	400
No. with third sound	231	37	268
%	71.08	49.3	67.0

It is considered that this figure of 67% forms a more accurate estimate of the incidence of the third sound among males of this age group than that obtained from Table I ($399 \div 59 = 488$ or 48.8%).

Some Features of the Third Heart Sound

Characteristics—These have been aptly described by various authors as "short and dull, a sort of thud" (Potain, 1856-1900), "dull shock rather than sound" (Thayer 1908, 1909). Potain further likened it to the recoil of a drum or the rebound of a hammer on an anvil. As a rule the third sound is of less intensity than either of the other two. However, Wolferth and Margolies (1933) remarked that occasionally it might be the loudest of the three, and this was found to be not unusual among the younger members of the present series. Frequently in the present series the third sound was palpable at the apex beat, sometimes it was visible also. In no case could it be more easily felt than heard even when a pronounced protodiastolic gallop rhythm was present. "Gallop" rhythm is usually described as being more easily felt than heard, but

it is possible that this is generally true only of the pre-systolic variety which results from the presence of a fourth sound.

Site of Maximum Intensity—The third sound is usually described as being heard best at or near the apex beat. Evans (1943), on the other hand, lays stress on the fact that in normal individuals he found it most audible in the fourth intercostal space, half-way between the nipple line and the left border of the sternum, in other words, a little internal to the mitral area. In every case in which I identified a third heart sound it was loudest at the site of the apex beat. When faint it was present at the apex beat only, when more prominent it could be heard with diminishing intensity for a distance of about 2 in (5 cm) outside the nipple area—in rarer cases even as far out as the anterior axillary line. As a rule it was heard furthest from the apex beat internally, along the left sternal border or along a line passing from the apex beat towards the pulmonary area; occasionally it was faintly audible in the pulmonary area itself. In a rather nervous young man of 23 it could be heard as high as the left sterno-clavicular joint, as far out as the mid-axilla, and as far to the right as the right sternal border. In another youth, aged 19, it was audible in the mid-axilla and beyond the right sternal border. In both, however, it was maximal at the apex beat.

Influence of Age upon the Third Sound—Previous writers have remarked upon the decreasing incidence of this sound with advancing age (Thayer, 1908, 1909; Evans, 1943, 1945), and this is clearly illustrated among the present subjects. Evans (1945) states definitely that it is never found in a healthy heart after the age of 40. However, the figures in Table I do not bear this out. Certainly in the sixth decade the sound is unusual, while beyond this age it is possible that it never occurs in the absence of disease. Thayer (1909) suggested that this increasing rarity of the sound with age might be explained by the comparative thinness and elasticity of the chest wall in the young and the absence of intervening lung. After the age of 40, and especially after 50, all the heart sounds become increasingly difficult to hear and their characters alter. They become shorter, more distant, and less resonant, often the first sound can scarcely be heard at all. It is not surprising, therefore, that the third sound, which is usually of much less intensity than either of the other two in healthy people, should be so difficult to hear in older subjects.

Influence of Posture—In only two of the 1,360 subjects could a third sound be heard at stage (i) of the examination—that is, with the individual erect. The ages of these two were 17 and 19, and both were of poor physique; in each case the sound was much louder with the subject recumbent. In some cases, examined after rising from recumbency, a third sound continued, but only so long as the pulse rate produced by the act of rising was maintained. Evans (1943) made similar observations on 125 normal hearts presenting a third sound, though in his series the sound persisted in the erect position in 13. However, all the patients examined by Evans had been sufficiently problematical to require reference to him for further opinion and were therefore, in a sense, selected.

Influence of Respiration—In the majority of the present series I found the third sound most audible in normal expirations, with forced expiration it often disappeared. Sometimes, usually among the older members of the series, it was most easily heard at about mid-inspiration. Unless very prominent it was absent at the height of normal inspiration, and in almost every case it disappeared on forced inspiration.

Influence of the Pulse Rate—The lowest pulse rate among those with a third heart sound was 48, the highest

132, the average 80. The last compared with an average of 76 in those without the sound. Bramwell (1943) also noticed no significant difference between the pulse rate of those with and those without the sound. Thayer (1909) considered the former to have a somewhat slower rate than the latter. He also gained the impression that the sound was more pronounced in subjects who had just lain down than in those who had been longer recumbent. I frequently noticed that a third heart sound would disappear as the examination of the recumbent patient continued. More often, however, a third sound would appear for the first time after the subject had been lying down for a minute or two. Again, the production of tachycardia by means of exercise, while generally increasing the intensity of the sound, would in some cases decrease it—occasionally causing the sound to disappear. All this suggests that in each individual there is an optimum pulse rate, varying from case to case, at which the sound is best heard. Probably the force of the heartbeats is just as important a factor in the production of the sound.

Influence of Blood Pressure—The average systolic blood pressure among those presenting a third sound was 135 and the average diastolic 70, among those without the sound it was 130 and 70 respectively. Hence the presence or absence of a third sound appears to be independent of the blood pressure.

Means of Intensifying the Third Sound—Thayer (1909) described various methods by which the third sound could be intensified. Raising the arms or legs, pressure on the abdomen, turning the subject on to the left side, and the production of tachycardia were suggestions he made. I found it possible to carry out only the last two as a routine in my cases, and there was no doubt that in the vast majority the sound was exaggerated in the left lateral position. The effects of tachycardia have been noted above.

The Significance of Type I Triple Rhythm

It is evident that an audible third sound at the apex beat, with the subject recumbent, is a common finding in health below middle age. It is not surprising, therefore, that it should happen to be present sometimes in a heart that is diseased, and its occurrence in such circumstances can surely be of no help to the clinician either in making a diagnosis or in forming a prognosis. On the other hand, it appears that a third sound, clearly and constantly heard in the erect position, is a rarity in a healthy heart and calls for the most careful investigation and consideration before being dismissed as of no significance. It may be that it usually is of some significance, and the louder the sound the more likely it is to be so. Even in the recumbent position a very loud third sound—that is, one as loud as or louder than either of the other two—appears to be unusual in men over 40, though not so uncommon in the young.

This influence of position as a means of distinction between a third sound in a healthy heart and in one that is diseased has already been remarked upon by Evans (1943). He also considered that in the presence of cardiac disease a third sound was maximal in the mitral area itself or external to it, whereas in the normal heart it was maximal internal to the mitral area. Since the third sound in the subjects reported in the present paper was invariably maximal at the apex beat I cannot agree that its presence in the mitral area has any significance.

White (1928) stated that "gallop" rhythm, in which term he included protodiastolic gallop resulting from a third sound, was always a sign of considerable gravity in civil life, and that during the 1914–18 war, when soldiers with effort syndrome were gathered together, a combination of pronounced tachycardia and a loud third heart sound

occasioned a minimization of the importance of gallop rhythm widely at variance with the appreciation of its significance in civilian practice. In the most recent edition of his book on heart disease (White, 1944) he asserts that protodiastolic "gallop" is more serious than presystolic. Now, among the present series of healthy males it was observed that what was usually required for a so-called protodiastolic gallop to be heard was an individual with both a third sound and a pulse rate of over 100. Furthermore, such a rhythm could be produced in many other subjects with a third sound by simply inducing a tachycardia by exercise. There was no reason to suppose that any of these people were sufferers from effort syndrome or that they might be so in the future. In other words, it appears that a protodiastolic "gallop" is not always a sign of gravity. On the contrary, it is heard quite frequently in normal hearts, especially among the young. When present in the recumbent position alone in a patient with heart disease it is probable that what is of significance is not the "gallop" rhythm but the tachycardia which produces it.

In certain of these men a type I "gallop" was present with a pulse rate of 90, in one it was heard with a rate of only 84. No doubt this production of a so-called "gallop" cadence with the slower pulse rate occurs when there is a longer interval than usual between the second and third sounds.

The Distinction between Type I Triple Rhythm and a Split Second Sound

It will be seen that no use is made of the term "reduplication," or, more correctly, "duplication." A heart sound is never duplicated. Either it is split into its normal components or an extra sound is present. The application of the term "reduplication" to both these phenomena, as usually happens, leads only to confusion.

Distinctions between a split second sound and an audible third sound are as follows: (i) the former is nearly always most obvious in the pulmonary area, while the latter has been found to be always maximal in the lower part of the praecordium—in my experience at the apex beat itself, whether the heart be normal or abnormal; (ii) splitting of the second sound is maximal on full expiration and, as I have found, on full inspiration, at both of which times, but especially the latter, a third sound is usually absent; but, what is most important, the cadence produced by a third heart sound is so characteristic that it should be impossible for anyone familiar with it to mistake the typical "lup-dupty" rhythm for a splitting of the second. Subjects in whom an audible third sound extends sufficiently high or a split sound sufficiently low show the two phenomena occurring in the same situation, the third sound clearly following the second component of the split sound. The cadence thus produced may be described as "lup-brupty."

Finally it is hoped that the time may not be far off when the standard textbooks devote more space to this and other forms of triple rhythm so that students may know what to expect and what not to expect from a normal heart.

Summary

The frequency of type I triple rhythm due to a third heart sound among 1,360 healthy Naval recruits and personnel is emphasized. The characteristics of the third sound, the site of maximum intensity, and the influence upon it of age, posture, respiration, and pulse rate are noted.

The usual insignificance of this form of triple rhythm, as judged from these findings, is noted.

Comparison is briefly made between this form of triple rhythm and a split second sound.

I am grateful to the Medical Director General of the Royal Navy for permission to publish this paper

SEVERE ERYTHEMA MULTIFORME

BY

I B SNEDDON, MB, ChB, MRCP

Honorary Physician to Skin Department, Royal Sheffield Infirmary and Hospital

Numerous papers describing cases of severe erythema multiforme have appeared in American and Continental dermatological literature. There is, however, a scarcity of reports in British journals, the most recent being that of Low and Davies in 1938. The comparative frequency of the syndrome is considered justification for the following case reports. In the early stages the disease may present itself as a sudden pyrexial illness associated with stomatitis which simulates diphtheria, Vincent's angina, glandular fever, or one of the exanthemata. Therefore a knowledge of the condition is of value to clinicians who are not pure dermatologists.

According to Beaudonnet (1894) the first description of the condition is said to have been by Alibert and Bazin in 1822. It has been rediscovered on several occasions, and each discoverer has coined a new name. Thus Fiessinger and Rendu (1917) called it "ectodermose erosive pluriorificielle," Stevens and Johnson (1922) "a new eruptive fever with stomatitis and ophthalmia," and Baader (1925) "dermatostomatitis." Lever (1944) surveyed the literature very fully and concluded that, on the evidence presented, the cases described under the above three names were all the same condition—erythema multiforme. He also suggested that some of the published cases of acute pemphigus and some instances of human foot-and-mouth disease in which laboratory confirmation of the diagnosis was not obtained were also examples of severe erythema multiforme.

I have seen and treated nine cases of severe erythema multiforme in the last four years—one in a child, seven in young adults, and one in a woman of 55. It is therefore not a great rarity. The following cases are described as illustrative of the disease.

Case 1

A single woman aged 25 was seen on Sept. 3, 1946, complaining of severe pruritus ani and vulvae of one month's duration. She had no past history of skin or allergic disease

and her only previous illnesses had been nephritis when 6, and anaemia, which had responded to iron therapy, when 21.

On examination the skin around the anus and vulva was sodden and excoriated, but no underlying cause was found. She was treated with a kaolin lotion containing 1% phenol and a dose of 100 r of superficial x rays to the affected areas. Phenobarbitone was given, 1/2 gr (32 mg) in the morning and 1 gr (65 mg) at night. The symptoms improved on this regime, and when she was seen again on Sept 17 the phenobarbitone was discontinued and another dose of x rays given. On Sept 23 the pruritus vulvae became more intense and the vagina became sore, causing discomfort on micturition. The following day ulcers appeared in the mouth and on the lips, she became feverish and felt ill with headache, backache, and malaise. Towards the end of the day a generalized eruption appeared on the trunk and limbs. On Sept 25 her temperature rose to 104° F (40° C), the eruption became worse, and a bilateral conjunctivitis started. She was therefore admitted to hospital.

On admission her temperature was 102° F (38.9° C), pulse 88, respirations 20. Her eyelids were stuck together by a glutinous mucopurulent exudate, her face was swollen and unrecognizable, the whole of the inside of her mouth was covered with a grey sodden pseudo membrane, and her lips were swollen and crusted. A diffuse eruption consisting of purplish red papules 0.5 to 1 cm in diameter was present on the trunk, but on the limbs it was frankly bullous. The bullae arose in the centre of papules, and none appeared on normal skin. Both palms and soles showed erythematous macules, with a few flaccid bullae on the tips of fingers and toes. The face and scalp were not involved. Nikolsky's sign was not present. There was a profuse vaginal discharge and the vulva and vagina showed shallow ulceration. The anus appeared normal. There was no enlargement of lymphatic glands, liver, or spleen, and no abnormality was found in the cardiovascular, respiratory, and nervous systems.

During the next four days her fever continued and a number of the bullous lesions became secondarily infected. Micturition was impossible without the help of warm vaginal douches. On the fifth day after admission her temperature returned to normal, her general condition improved, and the necrotic mucous membrane in the mouth began to separate. A few fresh bullae were still appearing on her legs, but most of the papular eruption on the trunk had faded and the conjunctivitis showed improvement. During the next week all the lesions improved rapidly, the ulceration of the lips being the most troublesome and the slowest to heal. She could now pass water without difficulty. On Nov 15, 21 days after admission, her mouth and lips were normal and all that remained of the skin eruption was faint erythematous staining and slight desquamation. The conjunctivitis had recovered completely and she had no recurrence of the pruritus ani and vulvae.

On Oct 26 the leucocytes numbered 11,000 per c mm (polymorphonuclears, 72%, lymphocytes, 22%, monocytes, 2%, eosinophils, 4%). Blood culture was sterile. Culture from vaginal discharge gave a growth of *β* haemolytic streptococcus and diphtheroids. Culture from the mouth gave a growth of *β* haemolytic streptococcus and *Staphylococcus albus* (coagulase-positive). On Oct 29 the leucocytes numbered 10,200. On Nov 5 the haemoglobin was 72%, and the erythrocytes 3,640,000 per c mm. A skiagram of the chest revealed no abnormality. The Mantoux test was 1/10,000 negative, 1/1,000 positive. Treatment consisted of local symptomatic measures and after the result of the bacteriological examination 1,200,000 units of penicillin were given intramuscularly from Oct 28 to Nov 2.

Case 2

A boy aged 9 was admitted to an isolation hospital on Oct 14, 1946. For a month prior to admission he had been run down and "nervy." Four days before admission his eyes became inflamed and swollen, and on the same day he bit his lower lip. The lesion on the lip became sore, and ulceration spread to the inside of his mouth. Two days later a few pink spots appeared on his upper chest, his eyes became more inflamed, and blisters were seen inside his mouth. His previous history contained no relevant facts.

On admission his temperature was 100° F (37.8° C) and both eyes were closed by swelling and sticky mucopurulent

discharge. The conjunctivae were deeply injected. A purulent discharge ran from his nostrils, which were crusted. His lips were swollen and crusted; the inside of the mouth was covered with a pseudo-membranous exudate, and a mixture of saliva and blood drooled from his lips. Slight enlargement of the cervical glands was present. There was a blotchy erythema on the face; discrete red macules covered the palms and soles, and a purplish maculo-papular eruption was present over the trunk and limbs. A few of the papules on the limbs showed a small central vesicle but no bullae were seen. No abnormality was found in the heart, lungs or abdomen. His condition remained unchanged for two days, but then his temperature fell and his general condition began to improve though at that time a urethral discharge was noticed for the first time. During the next week all the lesions healed except the mouth which showed shallow ulceration for a few days longer. He was discharged cured 26 days after admission.

On Oct 16 the leucocytes numbered 10,000 per c mm, the differential count being within normal limits. Culture from eyes, nose and mouth showed mixed staphylococci and streptococci and was negative for *C. diphtheriae* and Vincent's organisms. Culture of the necrotic mucous membrane from the mouth gave a growth of *Aspergillus niger*.

Treatment consisted of penicillin drops to the eyes, penicillin spray to the mouth and 40,000 units of penicillin intramuscularly four hourly from Oct 14 to 20. In addition he was given 40,000 units of antidiphtheritic serum on admission and 10 g of sulphamezathine in the first 24 hours.

Case 3

An able seaman aged 22 was admitted to a Naval hospital on March 28 1942. He complained of soreness of the eyes, ulceration of the mouth, and a rash on the arms and legs which had been present for two days. There was no history of drug-taking or of previous skin disease.

Examination on admission revealed severe purulent bilateral conjunctivitis, a grey sodden pseudo-membranous stomatitis involving the inside of the cheeks and the soft palate, and swelling and cracking of the lips. An eruption consisting of pink papules 1 cm in diameter surmounted by small central bullae was symmetrically distributed on the limbs but did not involve the trunk or face. The spleen was just palpable, this was the only other abnormality found. His temperature was 99° to 100° F (37.2 to 37.8° C) for a week, and at the end of this time all the lesions were clearing up. By April 22, 24 days after admission he had fully recovered.

The leucocyte count on admission was 6,200 per c mm, with a normal differential count. Culture showed no constant pathogenic organism, Vincent's organisms were not found. Treatment was symptomatic only.

Case 4

An ordinary seaman aged 21 was admitted to a Naval hospital on March 22 1943, with a history of two days soreness of the mouth and eyes, cough, backache and headache. There was no history of previous attacks or of drug taking.

On admission he had a temperature of 103.3° F (39.6° C). Acute mucopurulent conjunctivitis affected both eyes. The whole of the cheeks were covered with a greyish sloughing mucosa although there was no ulceration or bleeding. Three days after admission he developed a urethral discharge with excoriation of the glans penis around the meatus. On that day also he developed an eruption of large pink papules on the buttocks, thighs, and over the elbows. A few of these papules later developed central bullae. His condition remained much the same for the first week and then began to improve. He had completely recovered on April 20, four weeks after admission.

Culture from the conjunctivae showed no organisms. A throat swab produced a pure growth of *Staph. aureus* but no Vincent's organisms. The urine showed no abnormality. The leucocytes on admission were 23,500 but had fallen a week later to 11,600. The blood Wassermann and Kahn reactions were negative. A total of 29 g of sulphathiazole and 24 g of sulphapyridine was given from March 22 to 31 but without any appreciable benefit. Other treatment consisted of lotion and mouth washes only.

Case 5

A lieutenant, R.N.V.R., aged 32 was admitted to a Naval hospital on Oct 24, 1943. Four days previously he had had a slight cold in the nose and the inside of his mouth had become sore. This condition had rapidly progressed, and on admission he had gross stomatitis with desquamation of the epithelium over the palate and grey sloughing mucosa over the tonsils. The day after admission he developed a temperature of 101° F (38.3° C) and a leucocyte count was 13,800 per c mm. Sulphamezathine was given, but was discontinued after he had had 13 g, as a red papular eruption appeared on the arms and buttocks. This at first was considered to be a sign of intolerance, but was afterwards recognized as erythema multiforme.

On Oct 27 an acute conjunctivitis developed and his temperature rose to 103° F (39.4° C). The inside of his mouth was covered with sloughing epithelium and the lips were crusted, fissured, and bleeding. His temperature remained swinging between 99° and 103° F (37.2 and 39.4° C), and on Nov 2 he developed a urethral discharge, excoriation of the glans penis, and a pyoderma of the scrotum. The skin eruption was still very evident, and consisted of purplish-red papules, tender to the touch and hot, and confined to the buttocks and extensor surfaces of the arms and forearms. No bullae were seen. Two weeks after admission his temperature settled and all the lesions were by now healing. He was completely well five weeks after the onset. He gave a history of a similar attack in December, 1942, which had lasted two months.

The leucocytes rose to 15,200 at the peak of his illness. The differential count showed 74% polymorphs. The urine was normal, and sterile on culture. A swab from his conjunctiva produced no growth. A swab from the mouth on several occasions gave a growth of *Str. viridans*. There were no Vincent's organisms. Blood culture was negative. Apart from the small dose of sulphamezathine, treatment consisted of local symptomatic measures.

Case 6

A woman aged 55 was seen on Dec 3, 1946, complaining of the sudden onset two days previously of soreness of the mouth, throat, anus, and vagina, and a skin eruption affecting the neck, trunk, and limbs. Although feeling rather tired for a month previously she had been in good health, and had had no similar eruptions in the past. She admitted taking aspirin occasionally.

On examination she had a temperature of 102° F (38.9° C). An acute stomatitis with swelling and cracking of the lips was present. She also had rhinitis with excoriation of the nares, ulceration affecting the vulva and anus, and a profuse purplish maculo-papular eruption on the trunk, limbs, palms, and soles. A few papules had central vesicles. The conjunctivae were not affected. Her condition remained unchanged for seven days and then suddenly improved. Her skin desquamated severely during the recovery phase but she was normal 21 days after the onset.

The Course of Severe Erythema Multiforme

Severe erythema multiforme is an affection of children and young adults. The onset of the disease is acute, with a temperature up to 104° F (40° C), headaches, chill, malaise, and backache. Mucous membrane lesions are the first to appear, and the mouth is usually the earliest orifice to be affected. The primary lesion in the mouth is a flaccid bulla, but it is usually the later picture of extensive stomatitis, with pseudo-membrane which leaves bleeding erosions when it is removed, that is seen. Swelling of the face and the formation of haemorrhagic crusts on the lips add to the patient's misery. Tracheo-bronchial involvement, with the complications of oedema of the larynx and broncho-pneumonia, has been described, but was not seen in this series of cases. Bilateral conjunctivitis occurs in the majority of cases, and is often associated with a rhinitis causing crusting of the nares and epistaxis. Involvement of the genitalia is common and takes the form of balanitis with ulceration of the glans penis, urethritis, and in women ulceration of the vulva and vagina.

Within two to three days of the onset a skin eruption appears. A few cases in which the disease has been confined to the mucosae with absence of cutaneous lesions have been described, but in all the above patients a skin eruption occurred. The eruption usually begins on the extremities, and affects particularly the palms and soles, but at the height of the disease it may be generalized. The eruption is composed at first of macules and papules, but in the severe cases the lesions become bullous. Classical target and erythema iris lesions were uncommon in this series of cases. The disease remains at its height for a week and then the lesions begin to improve and the temperature falls. The conjunctivitis and the skin eruption disappear first and the ulceration of the mouth is usually the last to heal. The total duration of illness is three to six weeks. Unlike the common type of erythema multiforme, relapse is unusual, and according to Lever (1944) if subsequent attacks do occur they are milder. Despite the acute and alarming symptoms the mortality of the disease is low, only four fatal cases having been described in the literature. Complete recovery is recorded in the present cases, but this is by no means the rule, as many American authors have described ocular changes which have led to partial or total loss of vision.

The varieties of ocular inflammation have been well described by Bailey (1931) and Duke-Elder (1938). Duke-Elder describes three degrees of severity—the catarrhal, the purulent, and the pseudo-membranous. The pseudo-membranous conjunctivitis may heal without scarring, but can persist for years, causing conjunctival shrinkage, adhesions between the bulbar and palpebral conjunctivae and corneal opacities. In this stage it is indistinguishable from pemphigus vulgaris affecting the conjunctiva.

Differential Diagnosis

In the early stages of the illness many diseases may be simulated, including Vincent's angina, glandular fever, diphtheria, agranulocytosis, and the common upper respiratory infections. When the skin eruption has made its appearance the field is narrowed and only four conditions have to be considered in the differential diagnosis: drug eruptions, pemphigus vulgaris, dermatitis herpetiformis, and foot-and-mouth disease.

Bullous eruptions may be produced by several drugs, but they rarely affect the mucous membranes and do not usually present this clinical picture, although Moss and Long (1942) described two cases clinically identical with the present ones said to be caused by phenobarbitone. Raffetto and Nichols (1942) and Greenberg and Messer (1943) have also described a similar condition due to sulphadiazine. However, evidence that the drugs were the causal agents is scanty and they may well have been coincidental.

Pemphigus vulgaris is a disease of the elderly, its course is never as acute as erythema multiforme, and dramatic improvement at the end of a week is most unlikely. The eruption of dermatitis herpetiformis may simulate erythema multiforme, but general symptoms are slight, the conjunctivae are not affected, and its course is a chronic one. Human foot-and-mouth disease is a very rare condition, and although descriptions resemble those of erythema multiforme in that conjunctivitis, rhinitis, and balanitis may be present the skin lesions are confined to the area around the nails of the hands and feet. Laboratory proof of the presence of the virus is now possible by the Waldmann and Pape method.

Aetiology and Treatment

The investigations in the present series of cases have given no assistance in the search for the aetiology of severe erythema multiforme. Leucocyte counts were within nor-

mal limits or slightly raised. Differential counts showed no significant abnormality. Blood cultures were sterile. Bacteriological investigation of the secretions from the mouth and conjunctiva gave growths of only the common pyogenic organisms, and these varied from patient to patient and even from site to site in the same patient. *Aspergillus niger* was cultured in Case 2, but this is considered to be non-pathogenic. Only one of the patients had taken a drug—namely, phenobarbitone—before the illness started. Therefore drugs can be excluded as the main cause.

Most patients complained of feeling off-colour for some weeks before the onset, but no evidence of underlying sepsis or other infection was found. In its predilection for children and young adults, its self-limited course unaffected by therapy, and its benign outcome, the condition bears a resemblance to another disease of obscure origin—glandular fever.

After seeing this series of cases one has the impression of dealing with a definite entity and not just a variety of the erythema multiforme as described by Hebra, and it is not surprising that it has so often been described as a new disease. This is in accordance with French opinions, and the same view is also held by several American authors. However, until there is a more definite lead it is useless to speculate on the probable causal agent.

Treatment—The disease is self-limiting and treatment has little effect on it. Rapid recovery of the patients after a week's illness has led to claims being made by Weisberg and Rosen (1946) for the beneficial effect of nicotinamide and by Robinson (1945) for the effect of penicillin. However, although it appears to be reasonable to give penicillin for the control of secondary infection there is little evidence that treatment shortens the duration of the illness, which usually improves spontaneously at the end of a week.

Summary

A series of cases of severe erythema multiforme has been described.

The course of the disease, its differential diagnosis, and its treatment have been discussed.

Investigations have failed to throw light on the aetiology of the illness, but it is considered to be a definite entity.

I should like to thank the medical superintendent of the Derby Isolation Hospital for permission to publish the report of Case 2 and the Medical Director-General of the Navy for permission to publish Cases 3, 4, and 5.

A circular from the Department of Health for Scotland points out that though the majority of old people like to live in their own homes local authorities should help those who are unable to do so. Authorities have the power to provide domestic help in the home if necessary, and to build residential homes for the elderly who are unable to live independently. Not more than about 30 to 40 people should be accommodated in one home and such institutions should be brightly decorated and comfortable.

Medical Memoranda

Intravenous Atropine for Peptic Ulcer

I present here a case of ulcer of the lesser curvature of the stomach in which a crater the size of a cherry diminished to one tenth of its original dimensions after four weeks treatment and ceased to be visible radiologically after six and a half weeks.

An ex Serviceman aged 41 was discharged from the Army because of hyperthyroidism. In July, 1946, for two weeks he had pains in the epigastrium after meals. In October and November, 1946, the pain returned and was more severe. He was admitted to hospital on Nov. 18. The thyroid gland was slightly enlarged and a little hard on palpation. The basal metabolic rate was +11%, and there were no cardiac or ocular signs. A fractional test meal showed fasting hypersecretion with acidity 30/20 and 55/45.

FIG 1

the highest acidity after the introduction of 100 ml of 5% alcohol was 60/45 and 65/55. Stool examination for occult bleeding (benzidine test) was positive. A barium meal showed the presence of a niche the size of a cherry on the lesser curvature with regional gastric spasm opposite (see Fig. 1).

Under treatment the gastric complaints disappeared completely in 10 to 14 days. On the ninth day the benzidine test became negative. On Dec. 16 the ulcer niche on the lesser curvature diminished to one tenth of its original size and on Jan. 4, 1947 (after six and a half weeks), it ceased to be visible (Fig. 2). The highest acidity shown by fractional test meal before leaving the hospital was 50/40.

The treatment consisted of (1) slightly restricted mixed diet, (2) 1 oz (28 ml) of cod liver oil before breakfast, (3) 1 dr (4 g) magnesium trisilicate three times daily after meals, (4) radiant heat

FIG 2—Ulcer niche on the lesser curvature invisible

twice daily for 20 minutes on the upper abdomen. (5) daily intravenous injections of 1/60 gr (1 mg) atropine sulphate plus 10 ml of 10% calcium gluconate. After twenty-eight daily intravenous injections of atropine and calcium they were continued every third day, so that in all the patient received 35 injections.

COMMENT

The diet in this case was not very strict and the alkalization was not very massive. From my clinical experience it appears that cod liver oil before breakfast favours rapid healing of a peptic ulcer but I ascribe a great part of the therapeutic success to the intravenous injections of atropine. For many years the subcutaneous injections of 1/60 gr (1 mg) of atropine formed an integral part of my treatment. However I met resistant cases in which diet, alkalis, bismuth, cod liver oil, and subcutaneous atropine could not bring about a remission and operation could not be performed for various reasons. I then tried atropine 1/60 gr in 10 ml sodium bromide or calcium gluconate (10%) intravenously. The results surpassed my expectations. I admit that it is difficult to imagine, if one does not see for oneself, how different is the therapeutic effect of atropine injected subcutaneously and intravenously. The case described is an exact replica of cases published by me in *La Presse Medicale* in 1937. In my view intravenous injections of atropine sulphate in sodium bromide or calcium gluconate should form an integral part of the conservative treatment of peptic ulcer.

True Knot of the Cord giving rise to Foetal Distress

True knots of the cord are fairly commonly seen at delivery but are usually without effect on the foetus. The following case is of interest in that tightening of the knot in labour gave rise to an unexplained foetal distress in the first stage of labour.

CASE HISTORY

A primigravida at term was admitted to hospital on Jan. 18, 1947 as a case of foetal distress in the first stage of labour, with the cervical os dilated to admit only one finger. The patient had had a show at 3 p.m. the previous day, which was followed shortly afterwards by feeble and irregularly timed contractions. The vertex was presenting engaged in the left occipito anterior position, the foetal heart rate was 136, and the maternal pulse 64. Vaginal examination showed the head in the mid cavity, and the cervix not dilated. No liquor amni was draining. Labour continued throughout the night, with increasing uterine contractions, and at 9.15 a.m. on the 19th thick greenish brown stained liquor was passed. The foetal heart was found to be beating irregularly at 146, but subsequently fluctuated between 90 and 150. The cervix was dilated to the size of only one finger and no prolapse of the cord was palpable. Admission to hospital was requested, and this was arranged.

The progress of labour was confirmed, but no cause could be found for the apparent foetal distress. The foetal heart was observed for a while while beating irregularly in rhythm, it remained fairly constant at about 146 beats a minute, and was not unduly influenced by pains. Morphine 1/4 gr (16 mg) was ordered and the labour allowed to continue without interference. The foetal heart rate varied between 120 and 148, but became more regular in rhythm during the afternoon although thick meconium stained liquor continued to be passed at intervals. At 4.45 p.m. the cervix was dilated to four fingers and at 6 p.m. was fully dilated. Delivery of a mature infant weighing 5 lb 7 oz (2.47 kg) followed shortly afterwards. The cord was not encircling the neck, which fact probably saved the baby's life.

The baby at birth was limp blue-asphyxiated and covered with meconium stained liquor. The pharynx was cleared, and the infant responded slowly to efforts at resuscitation but ultimately became of a good colour. After delivery a true knot (tightly tied) was discovered about half way along the cord, which was 20 in (50 cm) in length. The placenta was normal. The neonatal period passed uneventfully, the baby subsequently being discharged fit and well.

I am indebted to the medical superintendent for permission to publish this case.

[illegible]

We are bound to add that the book has two other great defects. The first is that as in so many American works, the author bases his conclusions on the maximum number of cases however incompletely recorded whereas the intimate study of twenty well documented instances would often yield information of far greater value. The second fault is that the author appears to be ignorant of important British work on his subject. A book on kidney disease which knows neither Ellis on the Natural History nor Wilson on the 'Vicious Circle' is, to the British reader out of date before it is published. The expert who will read with discrimination seeking only histological fact and bibliographical information cannot afford to ignore this book. May it never fall into the hands of the beginner.

ROBERT PLATT

CHARMS THAT SOOTHE

Music in Medicine By Sidney Licht, M.D. (Pp 132 \$3.00)
Massachusetts New England Conservatory of Music, Boston 15

The importance of the arts in the treatment of disease has been the subject of several expositions in recent years. This book deals fully with the use of music in medicine. The following chapter headings indicate its scope: History of Music in Medicine, Philosophy and Psychology of Music, Music as Occupational Therapy, Psychiatry and Music, Background Music, Mealtime Music and Music in Bed.

The book contains some striking quotations and useful references but also much irrelevant material. However there are some amusing passages. Discussing music in operating theatres and dentists' chairs Dr Licht writes: 'There are times during an operation when delicate maneuvers become trying and the wrong music or increased volume might lead to exasperation.'

For many people drilling is a frightful experience. Some dentists have advocated the playing of music at a loud level during this procedure and of the treatment of arteriosclerotic psychosis. Oldtime favourites played softly for several periods daily is indicated. Obviously where specific musical numbers are requested, they should be played while

Alcoholics like to join in group singing, especially if the group is made up exclusively of fellow inebriates. He recommends too that 'live musicians should be used as often as possible.' Whether such observations are worth the export of three dollars to the hard currency area is a matter of opinion.

D V HUBBLE

Having no lexicographers ready to take on the task we in this country depend on the United States for comprehensive medical dictionaries. Our debt to American colleagues is great and must be acknowledged. Gould, Dorland, and Stedman, and their colleagues and successors have earned the gratitude of the whole English speaking profession. The latest of the long series is a reprint of the eighteenth edition of the *American Pocket Medical Dictionary* still bearing the name of Dr W A NEWMAN DORLAND as editor, it is published by W B Saunders Company at 10s and is also obtainable with thumb index for 12s 6d. In this edition the terminology has so far as possible been made to conform to that of the *Standard Nomenclature of Diseases and Operations* published by the American Medical Association. There are 1062 pages, printed for the most part in single column giving the pronunciation and brief definitions of all the principal terms used in medicine, surgery, dentistry, veterinary medicine, nursing and kindred sciences.

With the February number *Mother and Child* appears in a new and enlarged format. A leading article comments on a recent circular from the Ministry of Health concerning the weekly allowance for younger children as follows: 'In Circular 221/46 of the Ministry of Health there are stated a number of reasons why, in the opinion of the Minister, local authorities should take into account the payment of these family allowances and the recent increase in the rate of old age pensions when assessing needs in their various assisted services schemes. It has been said by a legal authority that in cases where many alternative defences are pleaded there is frequently no defence worth pleading at all. It occurs to us on a study of this circular that the Minister is in the same position. After saying it would probably be a breach of the law for local authorities to disregard family allowances the circular continues at very considerable length to state many possible reasons for disregarding such allowances. If in fact to disregard their effect is illegal why not say so? Can it be that the Minister has qualms of conscience with regard to this?' The price of the journal (which appears monthly) is 1s.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Nutritional Disorders of the Nervous System By J D Spillane, M.D., M.R.C.P. (Pp 280 20s) Edinburgh E and S Livingstone 1947

Includes accounts of vitamin B deficiency disorders, subacute combined degeneration of the cord, and nutritional neuropathy in wartime.

The Childbearing Years By C Scott Russell, M.A. F.R.C.S. Ed., M.R.C.O.G. (Pp 88 7s 6d) Oxford Blackwell 1947

A book on sexual physiology, child bearing, sterility and contraception for the lay reader, with many illustrations.

The Practice of Mental Nursing By Mary Houlston, R.G.N., R.M.N., R.F.N. (Pp 164 7s 6d) Edinburgh E and S Livingstone 1947

An introduction to mental nursing for junior student nurses.

The Psychology of the Unwanted Child By Agatha H Bowley, Ph.D. (Pp 112 6s) Edinburgh E and S Livingstone 1947

Includes a study of children in substitute homes, causes and effects of emotional rejection, and therapeutic methods.

A Handbook on Diseases of Children By Bruce Williamson M.D. F.R.C.P. 5th ed. (Pp 408 15s 6d) Edinburgh E and S Livingstone 1947

This edition includes new material on penicillin.

Libido and Delusion By Louis S London M.D. 2nd ed. (Pp 259 \$3.50) Washington, D.C. Mental Therapy Publications 1947

Discusses various theories of the libido, with reference to a number of cases, the pathogenesis of delusions and analysis of schizophrenics.

Suicide and the Meaning of Life By Margarethe von Andus (Pp 219 8s 6d) London William Hodge 1947

An investigation into the meaning certain individuals attach to their lives elucidated by personal questioning.

Le Déséquilibre Psychique By Dr J Borel (Pp 378 360 francs) Paris Presses Universitaires de France 1947

An account of mental imbalance, psychoses and delinquency, with clinical details.

Clinical Examination of the Nervous System By G H Monrad Krohn, M.D. F.R.C.P. 8th ed. (Pp 380 16s) London H K Lewis 1947

The chapter on angiography with perabrodil has been enlarged and illustrations have been added.

Veneral Disease By L Martindale, C.B.E., M.D. F.R.C.O.G. (Pp 31 2s) London The Association for Moral and Social Hygiene 1947

A simple history and description of venereal diseases with emphasis on their prevention by an appeal to morality.

Physicians Handbook By John Warkentin Ph.D., M.D. and Jack D Lange, M.S., M.D. 4th ed. (Pp 282 \$1.50) Chicago, Illinois University Medical Publishers 1946

A summary of diagnostic procedures.

Rh Its Relation to Congenital Hemolytic Disease and to Intra group Transfusion Reactions By Edith L Potter, M.D., Ph.D. (Pp 344 £1 10s 6d) London H K Lewis 1947

An account of the rhesus factor for medical practitioners with photographs and bibliography.

The 1946 Year Book of Dermatology and Syphilology Ed by M B Sulzberger M.D., and R L Baer, M.D. (Pp 638 21s) London H K Lewis 1947

The new material discusses BAL, penicillin in slow release vehicles, antihistamine agents and vitamin D for lupus vulgaris.

The 1946 Year Book of Industrial and Orthopedic Surgery Ed by Charles F Painter M.D. (Pp 429 21s) London H K Lewis 1947

Summarizes recent advances.

BRITISH MEDICAL JOURNAL

SATURDAY JUNE 28 1947

A M A CENTENARY MEETING

The centenary meeting of the American Medical Association at Atlantic City, New Jersey, from June 9 to June 13 will remain in the memory of those doctors fortunate enough to attend it as one of the most noteworthy events in their lives. The size of the meeting may be gauged by the number of medical men and women who registered—15,667. If we add those who omitted to register, foreign guests, and the wives and families of the American doctors who came from the 48 States of the U.S.A., the population of Atlantic City must have increased temporarily by at least 30,000. This was, of course, a record meeting for the A.M.A. The British visitor was astonished and at times perhaps stunned, by the sheer impact of the size of the meeting and by the large scale of its many notable assemblies and occasions—and not least by the open-handed and open-hearted generosity with which he was welcomed both officially and privately.

The A.M.A. meeting was like a landscape painting on a large canvas. The visitor was able to see the broad sweep of American medicine, and, if the pressure of people and events prevented him from seeing all the details, what he did see satisfied him that size had not been achieved at the expense of quality. The precision of the detail was indeed remarkable, and was seen to perfection in the scientific exhibits, which used every technical device to present the results of research in such a way that the general physician could understand almost at a glance the main facts of the subject demonstrated and the conclusions to be drawn from them. The legends to the exhibits were written in large script and exact language. Diagrams, charts, graphs, maps, colour photographs, drawings, x-ray films, anatomical models, surgical instruments, and mounted specimens were all assembled in a logical sequence that made each exhibit a balanced postgraduate course. An expert on the subject exhibited was there to expound and explain and to answer the ceaseless questioning of men and women eager for information. Some of the exhibits will subsequently be shown at meetings in the different States, but the exhibitors were not perturbed by the fact that several of the exhibits, the result of many months of work, would be only temporary. Medicine changes, and rapidly, is the American theme. In no other country is technology at such an advanced stage of development, and American medicine is almost spendthrift with technological devices. This may have disadvantages. Technology may in some instances be looked upon as an end in itself. The technological approach may lead to short-lived enthusiasms, and the patient may at times be only dimly visible behind a barrage of apparatus. In Great Britain the string-and-sealing-wax

tradition makes our approach to unsolved problems more cautious—an approach that leaves ample room for reflection. It is perhaps not fanciful to see in the bustling progress of American medicine the spirit of the frontier eager to deal quietly with the enemy and impatient of obstacle—a spirit that is aggressive, invigorating, and productive of results.

Those who represented the British Medical Association at Atlantic City were immediately made to feel at home, as indeed were all the British guests. Newcomers to the U.S.A. soon realized that what they had heard of American hospitality was no myth. There were of course the formal occasions common to all such meetings, but even here the lively friendliness of Americans diverted the formal pompousness. The B.M.A. delegation was given every opportunity to see the organization of the A.M.A. from the inside. They were invited to the dinner given to the Board of Trustees to the House of Delegates and then to the House of the A.M.A. They were presented to the House of Delegates at the opening of one of its sessions and then to the debates of this assembly which correspond to the Representative Body. The B.M.A. delegates were also invited to attend a meeting of the Board of Trustees to see the change of views on medical politics.

It may be of interest to outline briefly the structure of the A.M.A. The Board of Trustees corresponds to the Council of the B.M.A. It consists of nine members, one of whom serves for a term of five years, and the others for a term of one year, he is re-elected for a further year. No one, therefore, can be a trustee for longer than two years. The Board meets four times a year and its Executive Committee meets every month. The Board gives its stewardship to the House of Delegates, numbering not more than 175 members, like our Representative Body, and the House of Delegates sets policy. The County Medical Societies, of which there are more than 2,000, is the key unit of the A.M.A. Each Society consists of its county society and its city society. The House of Delegates elects members to the House of Delegates and the House elects the Board of Trustees. The work of the A.M.A. is carried out by Standing Councils and Executive Committees appointed by the House of Delegates. The work of the Councils is done at A.M.A. Headquarters in Chicago, each Council having a representative on the staff. There are, for example, Councils on the subject of research and hospitals, on industrial health, on the subject of medicine and grouped in one division is the Council on Medicine and Chemistry, the Therapeutics, the Council on Physical Therapy, the Council on Nutrition. There are a Bureau of Investigation, a Bureau of Officers are the Editor of the *Journal of the American Medical Association* and the *Annals of the American Medical Association*.

It was at a meeting of the House of Delegates that Dr. H. G. Dun, the Chairman of the B.M.A. delegation, presented to the A.M.A. a gift to the A.M.A. of the mulberry tree that grew in Charles Dickens's home in Finsbury Square, London. The tree, in company with the

guests were honoured subsequently by being admitted as Honorary Fellows of the A M A at the opening session of the meeting on June 10, an event also noteworthy for the concert given by the Philadelphia Festival Orchestra. The last item on this programme came as a pleasing surprise, for the conductor, Alexander Hilsberg, announced that it was to be the first performance of a march dedicated to the victory at Iwo Jima and composed by the President of the A M A, Dr Edward L Bortz. Later in the meeting the guests attended the President's reception and stood in the "reception line" to shake hands with many hundreds of American doctors and their wives. Before this reception a number of the guests, including the B M A party, were admitted honorary members of the Alpha Omega Alpha Club at its annual dinner. It is not possible to record in detail everything of importance that happened. One other event should be mentioned, however, and that is the addresses given on Sunday, June 8, and broadcast to the nation, by the Rev R C Hutehison, President of Lafayette College, Easton, Pa., by Rabbi J L Liebman, of Boston, and by Monsignor F J Sheen, of Washington, D C. During the meeting the Post Office Department issued 125,000,000 centennial stamps depicting the well-known painting "The Doctor," by Sir Luke Fildes, which is in the possession of the Tate Gallery. The House of Delegates elected Dr R L Sensenich as President-Elect, and Dr H A Christian was awarded the Distinguished Service Medal of the A M A. Finally, to round off in a permanent form the first hundred years of the A M A, the W B Saunders Company published the *History of the American Medical Association, 1847 to 1947*, by Dr Morris Fishbein, Editor of the *J A M A*. This 1,226-page volume contains biographies of the Presidents of the A M A, compiled by Dr Walter L Biering, and accounts by various authors of the work of the Councils and Bureaux of the A M A and of its publications. The Centenary Meeting is over. The written word remains in this "History" as an account of faithful stewardship and as an inspiration for the future.

THE PHYSIOLOGY OF VISION

The physiology of vision is a notoriously difficult and controversial subject, which although of great theoretical interest has at present little clinical significance. The common defects of colour vision are congenital and incurable. Those who suffer from them are unfitted for certain occupations, because their inability to distinguish between red and green signals would make them a danger to the community, or because the occupation is one which demands a well-developed colour sense. Such individuals can be identified without much difficulty and must be prevented from following the few professions and occupations in which their disability would endanger others. They should also be discouraged at an early age from aspiring to become painters or from entering branches of industry in which good colour vision is necessary or desirable. Great ingenuity has been exercised in devising simple tests for the rapid detection of these defects. A valuable critical review of tests for colour deficiency has recently been

published.¹ These tests are empirical in the sense of being independent of the truth or falsity of any particular theory of colour vision. Yet, although theories of colour vision and of the nature of "colour-blindness" may be unimportant for diagnostic purposes and valueless from the point of view of treatment, we believe that they do and should interest the medical profession. It is true that the disability caused by being unable to distinguish between red, yellow, and green is no great handicap in most walks of life. It has never been suggested that an attempt to reduce its incidence by discouraging the affected from becoming parents would be justified on eugenic grounds. But Pitts estimate² that such people can distinguish less than 30 colours differing from one another in hue and saturation, whereas a normal person can distinguish 5,000, is of great general interest and is insufficiently known. It is perhaps fortunate that affected individuals are necessarily unaware how much they miss of the rich and varied world of colour. Explanation of this curious anomaly necessitates consideration of the mechanism of normal colour vision.

Exactly 140 years ago a successful London physician and versatile genius, Thomas Young, published the final form of a theory of colour vision which he had adumbrated six years before. The essence of the theory, to which the name trichromatic has since been applied, is that there are three and only three fundamental or primary colour sensations—red, green, and violet (or blue). All other colour sensations, including white and yellow, are combinations of these three in varying proportions. "This supposition," he said, "simplifies the theory of colours. It may therefore be adopted with advantage, until it be found inconsistent with any of the phenomena." No serious writer on colour, before or since, has postulated fewer than three primary sensations in normal people. The only question that arises is whether there are more than three. To explain the physiological mechanism by which these sensations might be aroused when light falls on the retina, Young in 1801 had suggested a subsidiary hypothesis that "each sensitive filament of the nerve may consist of three portions, one for each principal colour." It is desirable to bear in mind these two tentative assumptions of Young, for neither necessarily implies the other. Since the middle of the last century, when Helmholtz in Germany and Clerk Maxwell in this country called attention to Young's brilliant suggestions, almost every writer on the subject has ranged himself either as a supporter or as an opponent of the trichromatic theory. The question of the number of different retinal receptors is another, although allied, problem. The discovery of rods and cones in the retina, two histologically and functionally distinct structures, has naturally had a great influence on the development of both aspects of the theory of colour vision. It would perhaps be true to say that physicists and psychologists have tended to be more interested in the colour sensations, while physiologists and anatomists have paid more attention to the retinal receptors and their central connexions.

¹ *Report on Defective Colour Vision in Industry* by a Committee of the Colour Group of the Physical Society. 1946. 52 pp. London. See also *British Medical Journal* 1946 2 948.

² *Characteristics of Dichromatic Vision*. Med Res Cncl Sp Rep Ser No 200. 58 pp. 1935. London.

Over the last twenty years most physiologists have favoured some form of the trichromatic theory. Hecht and Roaf, for instance, elaborated theories which, while differing profoundly from one another and from the "classical" theory associated with the name of Helmholtz, were alike in being trichromatic. Three books published in English within the last twelve months give it general support. Wright's³ contains a wealth of valuable and accurate data on the luminosity of spectral colours, on the facts of colour mixture, and on the discrimination of colours. It is argued that these are all consistent with, and most simply explained in terms of, three primary colour sensations. Willmer's⁴ is more speculative and less firmly rooted in personal researches, but is stimulating and provocative. Granit's⁵ brings together under one cover his important researches on the eye by electro-physiological methods. He shows, among other things, that individual fibres of the optic nerve are connected with receptors of several different types as judged by their responses to monochromatic light falling on the retina. Many receptors are sensitive only to a narrow range of spectral colour. Yet, although there is strong evidence for seven such "modulators," they fall into three distinct groups, corresponding with blue, green, and red light.

Prof. Hartridge, elsewhere in this issue (p. 913) and in his earlier articles,⁶ has sought to extend Granit's outstanding work to the human eye by studying the sensations aroused in himself when very small images of monochromatic light were formed on his own retina. He claims to be able to confine the stimulus to single cones or to small clusters of functionally identical cones. From these and other experiments, he concludes that there are not less than seven types of retinal receptor. The difficulties of explaining some of the facts of hue discrimination, colour mixture, and colour-blindness in terms of the trichromatic theory also lead him, as they have in the past led others, to postulate more than three primary colour sensations. If his arguments should, after careful scrutiny, be generally accepted, it will mean that the trichromatic theory has served its purpose as a useful working hypothesis and must now be declared, in the words of its originator, "inconsistent with the phenomena."

TREATING THE SYMPTOMS OF DEPRESSION

We have all experienced disturbances of affect, but with good fortune they are so short-lived and so mild that when the cause has passed our normal tranquillity returns without the help of treatment. As Stockings points out elsewhere in this issue (p. 918) the more severe disorders of mood make up a large part of general practice. The depressed and anxious patient, who may or may not have organic symptoms or signs, is so well known that he needs no description here. Whatever the exact pattern of the disturbance of feeling-tone that the patient has, there always exists the problem of how much of the disturbance is the result of difficulties the sufferer has encountered in his daily living and how much is the result of physical and perhaps constitutional changes within him. There was a

tendency once to refer to exogenous and endogenous depressions, but these terms lost favour when it was believed that in many instances the illness was compounded of endogenous and exogenous causes. The term "reactive depression" is still used, and some maintain that in any persistent disorder of affect—whether a depression or an anxiety state—the causes have inevitably arisen in the circumstances of the subject's life. There may be precipitating environmental causes but the predisposing causes are environmental too. Others recognize a precipitating cause or set of causes in such a case but maintain that the predisposition to the disorder was mainly inborn, and refer to evidence in the patient's family history and in his reactions to previous life situations to support this view. The recent dramatic results which have followed electric convulsion therapy in depressive illnesses, and particularly in involutional depressions, suggest that in these cases at any rate the illness has persisted as a result of a physical disorder.

In recent weeks and again in this issue (p. 921) our correspondence columns have shown among our readers some lack of unanimity on this theme. Stockings has no hesitation in referring to all these affective disorders as "the syndrome of thalamic dysfunction" and he believes that the illness is in fact the result of a disturbance in the behaviour of neurones in the thalamus and basal ganglia. He does not say. Although there are many who would not follow him all the way in such a direction, many would agree with his statement that in many cases of moderate and depression psychotherapy may be prolonged and even prolonged ineffective. Because of this we should seek for a treatment which will alleviate the distressing symptoms to the patient and the discouraged practitioner. It is favourable on a new and time-tested basis, namely, hexyl, pyrexyl or parhexyl. This has been reported upon by Adams in 1946, called to our attention which is taken because of the possibility of a side-effect which it induces. Synhexyl produces a state of anxiety and distress in normal people and in the case of depressed subjects found that in a group of 50 patients, 10 had no improvement and some with psychotic depression the effect was a further amelioration of the disturbance. In the case of 10 patients without similar improvement in the other 10 patients. In neurotic patients were helped more than in the case of 10. There were no immediate complications of the treatment and no sequelae. Caution is advised in the use of the drug, but since results with other drugs, such as benzodrine, are usually disappointing, it is worth further study. If it holds promise, it is to be hoped that we shall not forget the symptoms, and not causes. We do not know the cause of the pain until we know the cause of the pain.

TRIPLI CARDIAC RHYTHM

The third heart sound was first described by Osler in 1907. It is soft and low pitched, usually heard, and varies in intensity with the position of the patient. It is heard best at the apex beat, and is usually heard in the left side, especially in the supine position. It is raised by compressing the chest wall. In 1913 Osler proved that the third heart sound is associated with the lower part of the diastolic pressure. It is a phase of rapid ventricular filling. He also showed that it is a phase of rapid ventricular filling.

⁷ *Philosophical Transactions of the Royal Society of London* Series B, 1947, 232, 519.

that the sound was caused by the vibration of the ventricular walls set up by their sudden distension at this time.³ This explanation is now generally accepted. According to Orlans and Braun-Menendez⁴ the third heart sound begins 0.11 to 0.14 seconds after the commencement of the second heart sound. Margolies and Wolferth⁵ pointed out that this is distinctly later than the opening of the mitral valve, which coincides with the top of the V wave of the phlebogram.

Nothing is gained by calling a third heart sound "triple heart rhythm, type I a." Evans⁶ and other authors agree that the sound is very common in childhood, but not in infants, and becomes more and more infrequent with advancing age. O'Meara describes in an article published in this issue (p. 922) how he heard the third heart sound in 54 to 71% of 745 young men aged 17-20, and 35-49% of 255 men aged 21-30. His ability to detect the sound improved with experience. Its presence in the older groups is interesting (15.5% in 103 men aged 41-50, 5.7% in 70 men aged 51-60), particularly since Evans stated that a third heart sound is not heard in normal subjects over 40. Thayer⁷ reported a similar relationship to age. His figures for the second, third, fourth, and fifth decades were 84%, 60%, 42%, and 14% respectively.

The normal third heart sound may be confused with protodiastolic gallop, with the short diastolic murmur of active rheumatic carditis, with summation gallop, and with the opening snap of mitral stenosis. Protodiastolic gallop occurs when the third sound develops or reappears as a result of left ventricular failure. The murmur of active carditis should be distinguished with ordinary care. Summation gallop disappears when the heart is slowed. The opening snap of mitral stenosis is heard earlier and is more easily confused with a widely split second sound. The diastolic murmur of mitral stenosis is determined by the rapid ventricular filling phase, and may directly follow the opening snap or may be heard a little later.

SEVERE ERYTHEMA MULTIFORME

In 1860 Hebra⁸ separated from the collection of ill-defined erythematous eruptions described by Willan and others a group which he regarded as a clinical entity of obscure aetiology and called erythema exudativum multiforme. The eruption commonly affects the extremities and is characterized by erythema with which may be associated congestion, oedema and purpura, and sometimes vesication or bullous formation. The lesions are nummular, often target-like, and though Hebra did not mention the fact mucous membranes may be involved, especially in the vesico-bullous type of eruption. The incidence of such lesions is not less than 25% and is put by some authors as high as 60%, occasionally the lesions of mucous membrane are profuse and severe. Recurrence at variable intervals over the course of years is another common feature of the disease, and rarely the recurrences may be so frequent as to make the affliction a continuous one. The first attack of erythema exudativum multiforme is often associated with a fever, suggesting, perhaps, an upper respiratory tract infection, but subsequent attacks may be without such an onset. Toxic eruptions resembling the classical picture occur with other specific infective diseases and sometimes as an expression of sensitization to drugs.

Osler⁹ was impressed by the severity of visceral lesions sometimes accompanying the exudative erythema, especially the gastro-intestinal renal, and mucosal haemorrhages, and in reviewing a series of sixty-one cases from the literature, including six of his own, he found that thirteen patients had died from the disease. Under various names cases resembling the severe mucosal form of erythema exudativum multiforme have been reported whose notable features were severe eye complications from a purulent conjunctivitis, pneumonia of a non-bacterial type, and sometimes death. In all these cases there was a sudden onset, with serious constitutional symptoms, grave sequelae, and seemingly little tendency to recur. Rendu,¹⁰ using the term "ectodermose érosive pluriorificielle," regarded the group as a separate entity, while Stevens and Johnson¹¹ described the condition as a new disease hazardous to life and vision. Low and Davies¹² used Baader's¹³ term "dermato-stomatitis," and Dowling¹⁴ reported a series under the title of "a pemphigus-like eruption."

Stanyon and Warner,¹⁵ in a paper on the "mucosal respiratory syndrome," reported a non-bacterial pneumonia in fourteen out of seventeen cases of erythema multiforme, with two deaths. They emphasized the mononuclear character of the infiltration, animal investigations in a search for viruses were negative. The association of pneumonia with this disease was noted in a Report¹⁶ by the Commission on Acute Respiratory Diseases (Western Reserve University), where, in six cases of severe erythema multiforme three showed a non-bacterial pneumonia. Elsewhere in this issue Sneddon (p. 925) reviews some of these reports and describes a series of six cases. He draws attention to some features which this disease has in common with glandular fever. Keil¹⁷ reviewed the subject and maintained the unity of the benign and severe forms of the disease. Because of its mode of onset cases of severe erythema multiforme are commonly admitted to fever hospitals. Costello¹⁸ in a series of 75,000 admissions to the Willard Parker Hospital for Contagious Diseases found thirty-three cases of erythema multiforme of which seven were severe, three of these patients died. In his opinion penicillin was of value in preventing grave sequelae and death in some cases.

To sum up, severe erythema multiforme particularly affects children and young adults, has a sudden febrile onset, and severely affects the buccal mucosa, with frequent spread to the bronchial tree and sometimes to the gastro-intestinal tract. Conjunctivae and genitals are commonly affected and the lesions in these sites may lead to ulceration and scarring. Death has occasionally been reported. Whether this syndrome is a separate entity cannot be determined in the absence of a recognized causative agent, but the weight of evidence suggests that both benign and severe forms of erythema exudativum multiforme constitute a single and distinct disease entity.

The Humphry Davy Rolleston Lectures will be delivered before the Royal College of Physicians of London (Pall Mall East, S.W.) on Tuesday and Thursday, July 15 and 17, at 5 p.m., by Dr P. C. P. Cloake, F.R.C.P. His subject is "The Treatment of Disseminated Sclerosis by Artificial Pyrexia and Prolonged Administration of Arsenic."

The Main Entrance

THE OLD "BETHLEM" AND THE NEW SEVEN HUNDREDTH ANNIVERSARY OF FOUNDATION

Bethlem Royal Hospital, the first hospital to be established in Europe for the treatment of mental disorder, with the exception of one such asylum at Granada in Spain, is celebrating the seven hundredth anniversary of its foundation. When its history began, in 1247, it was as a priory for the sisters and brethren of the Order of the Star of Bethlehem. It is not clear from the records when it was first used for the insane. Some mention of this use is to be found at the beginning of the reign of Richard II (1377), and a Royal Commission in 1403 refers definitely to the confinement there of six persons of unsound mind (*sex homines mente capti*). This year is also the quatercentenary of the handing over of the institution by Henry VIII in 1547 (only 17 days before his death) to the City of London as a hospital for lunatics. For a few years after its transference to the City it was administered directly by the Court of Aldermen, but in 1557, along with Bridewell Royal Hospital, it was vested in the hands of a body of governors. This union was confirmed at a much later date by an Act of George III, and it continues to this day.

In the now distant past Bethlem had an unfortunate reputation for its treatment of lunatics. The contemptuous term 'Bedlam' is a corruption of its name. 'Sighing like Tom o' Bedlam,' says a character in *King Lear*—a reference to a common beggar who, because of lack of accommodation, was turned out on ticket of leave. Evelyn in his Diary 'stept into Bedlam,' where he saw several miserable creatures in chains, some of them, he added, were 'mad with making verses'. At one time Bethlem is said to have derived an income of £400 a year from the indiscriminate admission of visitors drawn by an idle and wanton curiosity, a practice stopped in 1770.

The Four Bethlems

The first Bethlem was the mediaeval foundation in Bishopsgate Without. At the close of the seventeenth century it was removed to a new site in Moorfields, where a building of some architectural merit, similar in design to the Tuileries, was put up. The third Bethlem, opened at the time when London was rejoicing over Waterloo, was built on eleven acres in St George's Fields, Southwark. This building with its copper dome, which in recent years became the Imperial War Museum, was a London landmark for more than a century. Here were transferred from Moorfields the famous two figures Raving and Melancholy, executed by Cibber, and said to have been portraits of patients in the hospital, one of them a porter to Oliver Cromwell. They evoked Wordsworth's line

"Bedlam, and those carved maniacs at the gates,
Perpetually recumbent"

Knight's *London* tells us that at the time when the hospital went across the river (1815) the patients were divided into three

categories: first the furious, mischievous and incorrigibly dirty; secondly, the ordinary and 'promoted'; and, thirdly, those advancing towards recovery.

The fourth and present Bethlem was opened in 1930 at Monks Orchard Beckenham ten miles from Charing Cross, in a wooded part of Kent. Here it has been possible to follow the plan of segregation rather than of congregation. Instead of one frowning building there is an estate with separate villas and generous gardens and the unit system enabling patients on reception to be placed with those having symptoms of a like character, replaces the heterogeneous assembly of the old days. There is accommodation for 250 patients who may be admitted on the voluntary, temporary or certified basis. Bethlem was a pioneer in voluntary reception as early as 1860 voluntary boarders were welcomed. At Monks Orchard there are a completely equipped surgical department, a pathological laboratory, units for hydrotherapy and electrotherapy, a recreation hall and workshops for arts and crafts, and the homely atmosphere of the living rooms and bedrooms.

gives point to the claim that whenever the word 'Bethlem' is now used it means 'curable'.

The Medical Hierarchy

The first physician whose name can be found associated with Bethlem is John Arundell, a medical ecclesiastic of the fifteenth century. He was physician and father confessor to Henry VI, who suffered from a mental malady for which Arundell prescribed a 'head purge' and possibly a cure and for his services—for Henry was restored to sanity—received the mastership of Bethlem. He was more priest than physician, he collected prebendal stalls in most cathedrals of England and died Bishop of Chichester.

From early in the seventeenth century the medical staff at Bethlem consisted of a non-resident physician in 'apothecary' and a visiting surgeon. The physician of course was supreme and even in the early nineteenth century there are records of the physician's leaving his instructions for the surgeon on a slate on the apothecary's door. One of the earliest physicians was Thomas Nurse, who had a large practice in Westminster in Charles II's time, and is buried in the Abbey. He was who first segregated the sexes at Bethlem. After Thomas Allen, an acquaintance of Pepys, there came Edward Tyson, scholar and philosopher, writer of some elaborate monographs on the dissection of animals. Tyson's portrait is in the Royal College of Physicians, his bust in All Hallows, Lombard Street, and his name is commemorated in Tyson House in the new Bethlem. He deserves it for with him a new era opened, though many of the old erudites remained. He paid attention to patients' dietaries, installed the first nurse, established an out-patient department and set up an after-care system. His instruction that patients should be treated 'with all the care and tenderness imaginable' was given 100 years before the chains were struck from the lunatics huddled in the Salpêtrière and 150 years before the metamorphosis of asylums for detention into hospitals for treatment really began. His successor, Richard Hile, was also a progressive man who considered company beneficial to the patients and joyfully recovered, and even a band of music contributors to the recovery.

Then came the remarkable dynasty of the Monros, one of the longest in medical history. It began in 1728 with James Monro, whom the *Dictionary of National Biography* describes as a skilful and honourable physician, though his policy of not admitting students or physicians to the practice of the hospital was the subject of criticism. He was succeeded by his son John, who instituted greater privacy and comfort for the patients and he in turn by his son Thomas who attended George III in his derangement and is said to have passed a hop pillow for the royal patient. With the retirement of the next in line, Edward Thomas Monro, in 1855, the dynasty ended, though Edward Thomas had a son Henry, not elected to the staff of the hospital, who was a noted neurologist.

Alexander Morison the first teacher of systematic psychiatry in Great Britain is another name associated with this period. Some of the humbler apothecaries were also noteworthy. One of them John Haslam, in 1789 gave the first account of dementia paralytica.

The first resident physician, as distinct from the resident apothecary, was Sir Charles Hood in 1852, he excluded criminal lunatics from Bethlem. In later years such eminent names as George Savage, Robert Percy Smith, Maurice Craig, Henry Rymer and many others have been associated with the institution. In 1914 the new designation of physician superintendent was made and a panel of consultants appointed. The long reign of J. G. Porter Phillips as physician superintendent will be fresh in the recollection. The present medical staff consists of the physician superintendent (Dr John G. Hamilton) senior and junior assistant physicians, a temporary assistant medical officer, a pathologist, the director of the psychological laboratory and a dental surgeon with a consulting panel of seven. The nursing staff comprises on the female side matron, deputy matron, seven sisters and deputy sister, 26 nurses and 18 part-timers, and, on the male side, chief and deputy chief and 28 male nurses. There are occupational therapy and physiotherapy officers.

For many years students were not admitted to Bethlem. The innovation was stoutly opposed until almost the end of the Monro era. In 1844 two students, one from St Bartholomew's and the other from St Thomas's, began their clinical studies at a fee of twenty guineas each, and some twenty years later the governors permitted the appointment of two resident pupils. To-day two house physicians in addition to clinical assistants form part of the medical staff. Classes of undergraduates and postgraduates from many hospitals and clinics have taken courses.

During the war a good deal of damage was sustained by the hospital. Much of it has been made good, though a wing of one of the houses will have to be rebuilt. The new Bethlem has been fortunate in its association with the City of London. Its president and great benefactor for many years was the late Lord Wakefield, one time Lord Mayor, after whom a unit is named. On his death in 1940 Queen Mary, who had taken a deep interest in the hospital for many years, became president, and it is hoped that Her Majesty will be present at the septucentenary celebrations, which are being held this week-end.

THE PROBLEM OF PHTHISIS

B.M.A. LECTURE TO ABERDEEN DIVISION

Dr R. R. Trail who is the medical director of Papworth Village Settlement gave a lecture recently to the Aberdeen Division of the British Medical Association in which he discussed a number of facts and problems concerning phthisis.

He spoke first of the placidity with which the community accepted the incidence of tuberculosis. "If we have two cases of anterior poliomyelitis or six cases of typhoid, newspaper headlines equal those given to a world crisis. No one, however, cringes from the house-tops the grim fact that Great Britain in 1945 had 22,945 deaths from phthisis, 206,939 cases under observation (an increase of 48,720 since 1939), and 50,482 new cases on the register. How many more should have been notified it is difficult to estimate. We know from the results of mass radiography surveys that there are at least a continuing 15,000 unsuspected but active cases in the supposedly healthy population for the age group 17 to 24. We gain nothing by hiding from the public and from ourselves that the incidence of active disease increases steadily after the age of 35, and that very large numbers of sufferers over the age of 30 are never diagnosed or if diagnosed are certainly not notified. There must be at least 150,000 men and women with positive sputum who are outside the sheltered conditions which could provide for their own safety and for the safety of their contacts in the home and in the community.

The Cost of It

The cost of schemes administered by counties and county boroughs in England and Wales for dealing with tubercu-

losis was nearly £4,000,000 in 1937-8, last year it was over £5,000,000. The bill for mass radiography was £200,000, family and maintenance allowances for tuberculous persons cost a further million, and tuberculous incapacity must account for at least one fifth of the £25,000,000 spent in sickness and disablement benefits. To this must be added some part of the £23,000,000 paid to widows and orphans by the Ministry of Pensions and some £2,000,000 in fees to insurance practitioners for attendance on the tuberculous sick in their own homes. The country as a whole was spending not less than £12,000,000 a year on this disease.

And what was the return for this expenditure? Some declared that sanatorium treatment was unnecessary, as large numbers of patients recovered without its aid, and useless as its end results showed it to be but a half-way house to death. Such statements ignored known facts. Sanatorium provision was a good middle part of treatment, badly let down by faulty supports at both ends, thanks in part to the strange lines on which tuberculosis services had developed. The tuberculosis officer had been encouraged to use his appointment as a stepping stone to that of medical officer of health. Outside the Lancashire, Welsh, National, and Middlesex and Surrey county schemes he had had little opportunity to rise in his own sphere. It should be made possible for every tuberculosis officer to interchange with residents in sanatoriums and village settlements and to rise to the position of physician consultant for his own or another regional scheme. After mentioning figures suggesting the value of sanatorium treatment, he said that while there was no room for complacency there was equally no justification for making a scapegoat of the modern sanatorium, which was, at least in the mechanical sense, completely successful within the limits imposed on it.

Mass Radiography

To the present state of affairs, in which 80% of sanatorium admissions were in stage B2 or B3, some would say that the answer was in mass radiography. Mass radiography was certainly the first step towards the discovery of an unsuspected but established lesion, but it was a long term policy in more senses than one. It was only in its beginnings there were far too few units. Again, if mass radiography was to act as a preventive measure by segregating or controlling previously unknown sources of massive infection, it required beds immediately following diagnosis or intensive work by expanded dispensary staffs, with visits to the patient's home. Without these provisions mass radiography, while spectacular was entirely useless.

Unfortunately the introduction of mass radiography has coincided with a decline in the number of institutional beds and the closing of some chest surgery units owing to lack of staff. People had been frightened instead of educated, given wrong ideas about infectivity, and had not had it impressed upon them that the well run sanatorium was the only place where they could avoid massive infection. The sanatorium had always two separate duties—a duty to the community in prevention through segregation, and a duty to the individual sufferer.

'Are we really cruel if, in our present desperate state, we refuse admission to all but those fit to benefit? All advanced cases were once early cases. The dying case occupies a bed for the same length of time as it takes to bring about arrest in three early cases (restored working capacity in two moderately advanced cases). Moreover, the prognosis of the adolescent and young adult case is unpredictable; it almost always requires active therapy. It is an ultimate contradiction to weed out sources of massive infection by mass radiography and to continue a system which replaces them.'

Psychological Considerations

One of the most striking things to emerge from a careful study of the statistics of mass radiography, Dr Trail continued, was the age group incidence of active disease—the high peaks in groups 17-24 and 35-39. In both groups many fresh lesions were found with no evidence of previous lung involvement. The story in the early group was in a significant proportion of cases of psychological difficulties, such as love affairs, family antagonisms, starting work on a distasteful job, and

on, in the later group the trouble was more physical and economic than psychological in its beginnings—the fatigue of long journeys to and from work, with strap-hanging and the like, worries over building society payments and children's education, fears for security in middle and old age. He ventured the view that the fact that many of the world's greatest poets had suffered from the disease was not due to any stimulus given by tuberculosis to poetic power, but rather in part to frustration and a disappointment with the response to their visions.

The neuro psychiatrist, the psychologist, and the social worker might give real help when called in by the medical superintendent, but the theory of some neuro psychiatrists that pulmonary tuberculosis was an 'escape mechanism' was to be contested. 'One easy error we must avoid, it lies in reading the mental reactions to any chronic illness as those of tuberculosis in particular, and in confusing them with the psychological stresses that preceded breakdown.' All chronic illness brought a sense of frustration, in phthisis this was especially marked. He considered that the best friend of the patient and of the medical superintendent was the understanding minister of religion. When the disciplines of religion in self-examination and self-control are added to those of medicine in the humane application of sanatorium treatment our patients have the opportunity to lose that sense of emptiness which makes meal times the outstanding events of the day and symptoms the main topic of conversation.

Social Factors Favouring Tuberculosis

Social factors which favoured tuberculosis were poverty, because it meant insufficient food and clothing and a meagre standard of living generally, the effect of war on civilians, with black-out and overcrowding and various deprivations, and slum conditions generally. A satellite town scheme would be welcomed by every thinking man and particularly by the medical profession. Social security offered insurance against breakdown, the fit were required to make bigger contributions towards the maintenance of the unfit, and some of the repercussions were already seen. To pay for these schemes taxes would have to be maintained on the 'necessary luxuries' of life such as tobacco and entertainment, so that real wages must go down. Such an effect might well keep up the incidence of phthisis, and this led Dr Trail into a discussion on the question of man power and the betterment of what had been called the 'climate of work' in order to assist production.

On his discharge from the sanatorium the patient was given well-meant advice, but the advice presupposed economic security, complete internal equilibrium, and a static order of life. The economic difficulties which drove the patient to continue working until his disease was advanced, and which worried him during his treatment, would not disappear on his return from the sanatorium, when he might find himself shunned by his neighbours and regarded doubtfully by his employer. His way was likely to be harder than that of the transgressor. To re-establish the status of the tuberculous implied psychological, physical, economic, and social restoration. Such a comprehensive scheme should be the ideal for the tuberculosis service of any region. For two groups in particular more must be done than was possible under present schemes—namely, those who were so interpreted as to be totally unfit for any work, although able to take restricted exercises, and the chronic type (the large majority) who could with safety to themselves be trained to work in sheltered conditions for six to eight hours a day. The former should be pensioned, for the latter the most acceptable condition was the village settlement.

The Village Settlement

In discussing the part played by the village settlement, supplying both rehabilitation and remunerative work for persons in this second group Dr Trail entered upon a detailed description of the Papworth settlement in Cambridgeshire. He mentioned that in 1946 Papworth had a turnover of £415,000 with a profit of £18,000. Here the patients regained their self-respect through work which enabled them to support them-

selves and their dependants, and returned to community and family life. None of the children born at Papworth who had reached adolescence and young adult life had so far developed phthisis and 70 of them served in H.M. Forces during the war. The late Mr Neville Chamberlain, when Minister of Health, said that Papworth pointed the way to the mitigation or solution of a very grave problem, but few local authorities had taken his advice to repeat the experiment.

'The village settlement is, I believe' said Dr Trail in concluding his lecture 'the only possible present answer to the problem of phthisis. It will be many years before we see the age of prevention with ideal garden cities where our people educated in the laws of health, are satisfied and happy because they have both economic security and a good climate of work.' This does not excuse us from our present duty to the tuberculous, which lies in supplementing their physical treatment with real rehabilitation using their untapped powers of production, giving them a chance to maintain their morale and self respect, and saving their families to be the future teachers of our faith.

To the authorities who said that the expense of a Papworth was too great he pointed out that any new settlement must grow, as Papworth did, round its sanatorium and first workshop. Even at present costs a settlement for 30 patients comprising the necessary land, 10 cottages for married colonists, a hostel for 20 single settlers, and a factory with a capacity for 60 workers could be established for £50,000 and be self-supporting in its industries within ten years of its establishment.

SUPERANNUATION IN THE NATIONAL HEALTH SERVICE

DRAFT REGULATIONS

The draft of the regulations governing superannuation in the National Health Service which the Minister of Health proposes to make subject to the approval of both Houses of Parliament has now been published. The whole subject matter of these regulations has been under discussion between officers of the Ministry and a subcommittee of the Negotiating Committee since the comprehensive discussions with the profession began. Although as a result of the representations by this subcommittee, there have been very substantial improvements in the details of the proposed scheme neither the Negotiating Committee nor the profession are in any way committed to these proposals. Nor indeed will there be any commitment to any part of the Government's proposals under the National Health Service Act until the profession as a whole is apprised of all the details including the Minister's replies to its representations and until through its own machinery the views of the profession have been ascertained.

The work undertaken by the subcommittee on superannuation has been to secure improvement in the terms offered without prejudicing in any way the decision which has yet to be reached by the profession. The Minister having decided to issue such regulations covering all branches of the Service institutional and non institutional medical and non medical the role of the subcommittee was to discuss without commitment. The Negotiating Committee will consider the report of the Superannuation Subcommittee simultaneously with and in the light of the reports of the other subcommittees which were set up for the purpose of the comprehensive discussions with the Ministry on the Act and the Regulations. Reference is made to these subcommittees in our leading article of June 14 (p. 853). The main features of the draft regulations as they apply to doctors, are here summarized.

Two Schemes

The proposals fall roughly into two schemes.

I.—*The Central Health Services Scheme* which will apply to (a) practitioners employed by regional hospital boards, boards of governors of teaching hospitals, and by other bodies constituted under the Act except local health authorities. (b) salaried practitioners and their assistants on the lists of executive councils and part time specialists who are not devoting substantially the whole

¹ Draft Rules and Orders, 1947. National Health Service. H.M.S.O. 1s. 6d. net.

of their time to specialist services under the Act (Those specialists who are substantially whole time in the Service will be included in category (a) above)

II—The Local Health Services Scheme, which will include the medical officers employed by local health authorities. These practitioners will be subject to the Local Government Superannuation Act 1937 but the benefits of that scheme (or of a local Act scheme where it applies) will be replaced by the benefits of the Central Health Services Scheme with an option for existing officers to remain subject to their present superannuation scheme

The inclusion for the first time in statutory superannuation arrangements of medical and dental practitioners in general practice has necessitated special provision in the draft regulations for this branch of practice. So far as medical practitioners are concerned the broad concept of category I (a) is the whole time or mainly whole time officer on a salaried basis, whose pension will be assessed on average remuneration during the last three years service. General practitioners and others in category I (b) will have their pension assessed, in general, on the remuneration over all the years of service.

These draft regulations comprise a formidable and abstruse document of some 88 closely printed pages, and in the space available it will be possible to deal with only the main provisions in general terms.

Contributions

The new scheme is on a contributory basis, the contributions payable by the practitioner and by the employing authority being 6% and 8%, respectively, of his remuneration. A principal on the list of an executive council will be required to pay the employers contribution in respect of an assistant in his employ.

A practitioner leaving the Service, whether by voluntary resignation or otherwise (except in cases of fraud or misconduct related to his duties), and who is not entitled to pension or allowance will have his contributions refunded with compound interest at 2½% per annum.

Benefits

(i) Practitioners employed by regional and teaching hospital boards—Category I (a)

PENSION for each year of contributing service 1/80th of average remuneration (maximum pension 40/80ths)

RETIRING ALLOWANCE for each year of contributing service 3/80ths of average remuneration—subject to reduction to 1/80th for each year in the case of a married man to provide for widow's pension (maximum retiring allowance 120/80ths)

AVERAGE REMUNERATION for this purpose is the annual average of the remuneration for the last three years service with the employing authority

(ii) Practitioners on executive council lists and part time specialists—Category I (b)

PENSION for each year of contributing service 1½% of the remuneration for that year (if more than 40 years contributing service, only the last 40 years will be reckonable)

RETIRING ALLOWANCE for each year of contributing service 4½% of the remuneration for that year, with limitation to last 40 years as for pension, subject to reduction to 1½% in the case of a married man to provide for widow's pension

Mixed Service—Where a practitioner in public general practice is simultaneously employed as an officer of an employing authority in some other capacity—e.g., as an officer of a regional hospital board—his remuneration in respect of his 'non G.P.' service will count as general practice remuneration for the purposes of pensions and allowances

Where a general practitioner has previously been an officer—for example of a regional hospital board—and his service in that capacity does not exceed 10 years remuneration in respect of that service will count as general practice remuneration for pensions and allowances purposes

Where the reverse applies and an officer of a regional hospital board has had previous contributing service as a general practitioner, his pension will be made up of two parts, one in respect of the general practitioner service on the basis of 1½% of each years remuneration, and the other in respect of the salaried service on the basis of 80ths of his average remuneration assessed on the last three years salaried service. The retiring allowance will also be made up of two parts the calculations being made as set out under (i) and (ii) above

(iii) Widow's Pension

There will be payable to a practitioner's widow one third of the pension he would have received had he retired from the Service at the date of death or one-third of the pension he was receiving if he was a pensioner when he died. The widow's pension will cease if she remarries or cohabits with a man as his wife

(iv) Incapacity Pension

A practitioner who has completed ten years service and whose employment ceases by reason of permanent ill health or infirmity of mind or body will be entitled to a pension. Where, on incapacity, service is over five years but less than the ten years required for an incapacity pension, a short service gratuity will be payable by the Minister

(v) Other Allowances

There is also provision for death gratuity and injury allowance, where injury resulting in permanent incapacity has been sustained on duty, of "such amount as the Minister considers reasonable, not exceeding two thirds of his average remuneration, having regard to all the circumstances of the case"

Qualifying Periods

The benefits of the scheme are all dependent upon the completion of prescribed qualifying periods of service. These are (a) for pension—10 years' service on or after age 60 (55 for mental health officers), (b) for retiring allowance—5 years service on or after age 60, (c) for widow's pension—10 years service, (d) for death gratuity—5 years service, (e) for incapacity pension—10 years service, (f) for short service gratuity—5 years' service

Retirement and Re employment

"Pensionable age" in relation to a practitioner on the list of an executive council is the age of 65 years or "such later age as the Minister may in any particular case allow," and in relation to other practitioners is 65 years of age (60 for mental health officers). In both cases there is an option to retire at 60 (55 for mental health officers), provided 10 years service has been completed

Practitioners on the lists of executive councils who continue in the Service between the ages of 65 and 70 will be entitled to receive both full pension and full earnings. Those who continue in public practice beyond age 70, however, will receive either the pension to which they are entitled or their average or final remuneration, whichever is the greater

Other practitioners (i.e., those not in category I (b)) who are re employed in the public service after attaining pensionable age will be subject to the general principle governing this situation—the remuneration and pension taken together will be limited to the average or annual remuneration received before the pension became payable

Practitioners with Existing Insurance Commitments

A general practitioner, an assistant, or a part-time specialist who is in category I (b) who has already committed himself to a policy of insurance with any of the Life Assurance Companies, and who joins the Service on the appointed day, may opt out of the superannuation scheme. Application for exclusion from the regulations must be made to the executive council within three months of the appointed day and will be subject to the Minister's approval. Where approval is given the Minister, subject to certain safeguards to be prescribed, will pay to the practitioner the employer's contribution of 8% of his remuneration to enable the existing insurance commitment to be maintained

Transfer and Interchangeability

The scheme provides a considerable measure of interchangeability between the various parts of the health services and other services which are subject to statutory superannuation schemes, including the Civil Service and the Local Government Service. There is no provision, however, for a medical officer who transfers from the Local Government Service to University Service

Any questions arising out of the regulations will be determined by the Minister

Nova et Vetera

LITERARY SURGEONS

In a recent oration delivered before the Hunterian Society Mr Zachary Cope discussed the association of surgeons with literature. It was not remarkable, he said, that few surgeons in the early days showed literary leanings. The surgeon in Tudor times was, with few exceptions, an uneducated person working under the direction of a physician, as a rule an ecclesiastic. Even when the scope of surgery increased the man who performed mutilating operations on fully conscious patients was scarcely likely to be of the contemplative, poetical, or imaginative type in whom literary sympathies were to be expected, and later still, with the coming of anaesthesia and antiseptics, though a vast field was opened up in surgery and many brilliant men were attracted, they had little leisure to cultivate other pursuits.

The first name mentioned by Mr Cope was William Clowes (1540-1604), surgeon to St Bartholomew's, who gave a rhyming introduction to his *Proved Practise for all young Chirurgions* and the same propensity for rhyming was found in John Woodall's *Surgeon's Mate* (1639). Two Continental military surgeons, Ambroise Paré (1510-90) and Larrey (1766-1842), wrote absorbing accounts of their journeyings and adventures on military campaigns. Larrey's description of Napoleon's entry into Moscow and the retreat had thrills to satisfy the greediest appetite. The first president of the Hunterian Society, Sir William Blizard (1743-1835), was a prolific writer in rhyme or blank verse, and Sir Norman Moore declared that his rhymes would have qualified him to appear in Pope's *Dunciad*. Another surgical versifier of the period was William Wadd (1776-1829), who wrote certain rather trivial and unoriginal books. James Hinton (1822-75) wrote philosophical books, and of him Thackeray said, "Whatever else he can do, this man can write." Volkmann, the German surgeon in the Franco-Prussian War, was a writer of delightful fairy stories, some of them composed outside Paris during the siege. An English surgeon of the same period, Sir Henry Thompson (1820-1904), in addition to exhibiting on twelve occasions in the Royal Academy, wrote two novels, one of them having for its startling theme the recognition by a medical student of his aunt's face in a dissecting-room subject. Perhaps Thompson's most remarkable achievement was his publication at the age of 82 of an elementary handbook on the nature, use, and management of the motor-car.

More modern personalities were Frederick Treves (1853-1923) and Stephen Paget (1855-1926). Treves had an attractive literary style and his *Other Side of the Lantern* was still a best seller. Paget wrote a series of biographies and several books of essays, "quotable for hours". Mr Cope specially recommended his *Confessio Medici*, and in that book the essays headed "The Spirit of Practice" and "Wreaths and Crosses". Two other surgeons, still more lately gone from us, are D Arcy Power and Wilfred Trotter. D Arcy Power furnished 184 medical memoirs to the *Dictionary of National Biography* and was for a time president of the Bibliographical Society and of the Pepys Society. Wilfred Trotter was a philosophical writer with a great influence on his contemporaries, and his slender volume of essays, collected and published posthumously, was packed with clear thought and memorable for many felicitously expressed and stimulating sentences. Another surgeon who wrote essays full of good sense, kindness, considerable learning, and respect for the best kind of tradition was Harvey Cushing.

Mr Cope then mentioned a number of living surgeons, first of all the doyen James Johnston Abraham, who early in his career gained a literary reputation by the publication of *The Surgeon's Log* for a new edition of which there had been a call almost every year since its publication. His biography of Lettson, his novel *The Night Nurse* and his light essays under the title *Ninety nine Wimpole Street* revealed his versatility. Geoffrey Keynes was distinguished as a literary critic, an editor of standard works, and a bibliographer. Kenneth Walker was a versatile writer whose earliest book was written for children, and whose autobiography, *I Talk of Dreams*

stood in many respects alone in autobiographical literature. Finally there were the philosophical books of K W Monserrat, the fine poetry and witty causerie of Oliver St John Gogarty, Chevalier Jackson's extraordinarily interesting autobiography, Scott Stevenson's vivid pen-portrait of Morell Mackenzie, W E Tanner's faithful account of his teacher Arbuthnot Lane, and James Berry's historical resurrection of his distinguished ancestor. The profession of surgery had produced especially during the last hundred years, a number of cultured men of high and in some cases outstanding literary ability—essayists, biographers, descriptive writers, novelists, philosophers, minor poets, and at least one famous bibliographer.

Preparations and Appliances

A TAPER TYPE INFLATOR FOR ANALSTHETIC MASKS

Dr A OWEN-FLOOD Hornsey, London, N 8, writes

I have never been on good terms with the conventional inflatable anæsthetic mask. It is definitely—and especially when made of synthetic rubber—bad value becoming useless after a short period. Its long vermiform appendage of rubber, through the lumen of which one blows lustily to inflate the cushion, inserting with haste an ill fitting bone bung, deteriorates rapidly and renders an otherwise serviceable mask unreliable and prone to leak, usually at awkward moments—when giving oxygen under pressure in cases of asphyxia.

The taper-type valve illustrated here is firmly seated into the body of the cushion. With the taper pin lifted from the valve seating by unscrewing the milled head (a few turns anti clockwise) the mask is readily inflated by means of a 20 ml syringe, the nozzle of which fits snugly into a slot in the milled head. The mask, part of which appears in the photograph, has been in continuous use in my out-patient department for the past twelve months. It has given excellent service,

FIG 1—Taper valve, mounted

FIG 2—Taper valve, exploded x4

FIG 3—Taper valve inflator (not to scale). A—Taper washer, B—Valve seating, C—Inflator control knob

needing inflation on only two occasions. It is still in excellent condition. Any instrument makers interested in this device can have full blueprints from me.

Reports of Societies

SYMPATHECTOMY

At a meeting of the Section of Anatomy and Physiology of the Royal Academy of Medicine in Ireland on March 21, with Prof O'Connor in the chair, Dr V E C HAMILTON read a paper by Prof H Barcroft and himself entitled 'The Results of Sympathectomy'.

There had been three main phases in the evolution of operations for the sympathetic denervation of the upper extremity: periarterial sympathectomy, cervico dorsal ganglionectomy and the preganglionic operations of Telford and Smithwick. Methods of investigating sympathetic activity included sweating reactions, the psychogalvanic reflex, and skin resistance measurements dependent on reflex sudomotor activity, photo electric plethysmography and venous occlusion plethysmography dependent on reflex blood vessel responses, and skin temperature measurements, which were dependent on both reflex vasomotor and reflex sudomotor activity. Venous occlusion plethysmography was preferred as the post operative test to determine whether any sympathetic activity remained.

Hand blood flows were measured using the venous occlusion plethysmograph in 28 limbs sympathectomized by the Smithwick operation. Reflex vasodilatation was tested for by two methods: (a) feet heating, and (b) anaesthetization of the radial, ulnar and median nerves in the arm, which temporarily interrupted also the sympathetic nerves to the hand. The results obtained by these two methods were invariably in agreement. Sixteen sympathectomized hands showed complete absence of vasomotor control at the time of testing, 12 hands showed the presence of a slight degree of vasomotor control much less than that possessed by normal hands. A possible explanation of the 12 partial failures was that a partial regeneration of sympathetic pathways had occurred. From the clinical aspect the results were very good, only one patient considering that operation was not worth while. Complete relief of vasospastic symptoms occurred in 16 hands though attacks of the Raynaud phenomenon had been frequent before operation. In 10 hands attacks had been less severe and/or less frequent, in 2 hands as frequent and as severe and in no case had attacks been more frequent or more severe after operation.

Some Difficulties

Mr P FITZGERALD said that the difficulty of performing an efficient dorsal sympathectomy, due to the inaccessibility of the chain, almost certainly accounted for some unsatisfactory results, while others were probably due to anatomical variations. Regenerations were also likely, since the gap between the segmental supply and the postganglionic fibres was small in this region. Major relapses were probably due to faulty operative technique while minor relapses could be due either to regeneration or to persistence of unusual pathways. The most marked feature in all cases from the clinical point of view appeared to be the relief of pain, which in serious cases might be distressing. The pain pathways might possibly be mediated through the sympathetic nervous system.

THE PNEUMOCONIOSES

At a meeting of the Section of Medicine of the Royal Society of Medicine on May 27 Dr MAURICE DAVIDSON presiding, a discussion was held on pneumoconiosis.

Dr E R A MEREWETHER said that the 500 deaths which still occurred every year due to pneumoconiosis were a challenge to medical men and to all responsible for the control of this disease. Pneumoconiosis, according to the Workmen's Compensation Act 1943, Sect 1 (2) meant fibrosis of the lungs due to silica dust, asbestos dust or other dusts and included the condition known as dust reticulation, but many medical men as well as laymen took a less precise view and argued that it included any infection of the lungs produced by dust. The meaning must be made plain when using the word particularly in the medical certificate or radiological report, or difficulties and disappointments would arise if possi-

bilities of compensation were discussed when none existed. Using the term "pneumoconiosis" in its legal meaning he was led to the question of diagnostic criteria. Here reliance must be placed upon the nature of the occupation and the radiological picture. The results of the clinical and the radiographic examination might be of doubtful significance, but the occupation, if thoroughly investigated might carry conclusive weight in conjunction with the other examinations.

The question of radiographic appearances needed reassessment. Consideration must be given not only to the purely radiological technique, but to the determination of the limit of normality—the differentiation between abnormal markings indicating the presence of dust but with no disease present, and those indicating the presence of dust together with disease. Fifteen years ago the radiological appearances of asbestosis were considered by leading radiologists as coming within normal limits, but now a stage had been reached in which they were involved in more difficult matters of interpretation of dusts which merely produced shadows without disablement or disease and those which had a more sinister significance. In the past radiography had been emphasized chiefly as an aid to diagnosis, now it had to be developed as an aid to the assessment of disablement and a guide to prognosis. Both these aspects had lately increased in importance because of increased compensation, the rehabilitation measures set up under the Disabled Persons Act, and the provision of employment for pneumoconiotics.

A great deal more knowledge was needed concerning incidence rates in occupations, because these would provide an index to the efficiency of preventive measures. Both the risk of silicosis and its severity when it occurred varied very much in different occupations. Much was said of its incidence in coal miners, but from a rough calculation it appeared that the mortality from the disease among sand blasters was greatly in excess of that among coal miners. More data were also required on the effects of massive exposure to the commoner dusts.

Dr CHARLES FLETCHER described an investigation he had carried out in South Wales into cases of men who had been certified as suffering from pneumoconiosis during the last twelve years, 60% of them were under the age of 50. The number of certifications was 15,000. Why had this situation developed? One factor had been the ignorance of medical men, who had assumed the condition to be bronchitis and not silicosis and had not taken steps to prevent it. On x-ray examination of some of these cases it was found that simple reticulation, or the diffuse lung disease, tended to remain stationary, though there were cases in which coalescing shadows went on developing relentlessly. These were cases which had left the pit after the first x-ray examination, so that the progress was not caused by continued exposure to the dust. The progress was nearly always associated with a high sedimentation rate, which suggested that an infection might be responsible. Only 3.5% of the cases with massive shadows showed a positive sputum, when there was a positive sputum the prognosis was poor. Surveys of various kinds were still to be made, together with therapeutic trials.

Subclinical Silicosis

Prof MATTHEW STEWART spoke on the question of subclinical silicosis. It was not sufficiently realized how effectively a healthy man could get rid of the dust. Cases were encountered in which there was a large accumulation of dust in the trachea and in the bronchial and hilar glands, and yet there was very little evidence of silicotic disease. In one series of cases the silicosis occurred only in the lymphatic glands. The difference between the morbid anatomy of silicosis and of asbestosis was interesting. Why should asbestosis be so diffuse as compared with silicosis? Why should it be so marked at the lobes and at the base of the lungs? The theory he had formed was that it was a question of the chemical action of the two dusts. The dust in silicosis was very fine, with little rounded particles of regular shape whereas the asbestos dust was fibrous and could not be inhaled directly into the lungs in the same way as silicosis dust, the mode of entry being by gravitation.

In some further discussion Dr BROWN of Newcastle suggested the existence of a large undiscovered field of this disease in North east England. Dr HORACE JOULES

suggested that, in view of the frequency with which Welsh miners came to London and became milk roundsmen, mass radiography for all milk roundsmen should be introduced. Dr JACOBS said that there had been too much complacency in the medical profession with regard to the presence of large amounts of dust in the lung. Dr PHILIP ELLMAN referred to the early development of symptoms in asbestosis as compared with silicosis. Several cases he had encountered had developed within from one to three years. The seasonal incidence was noteworthy, during the winter months tenacious sputum containing asbestos bodies was found.

Dr MEREWETHER pointed out that the powers under the new Act were very wide, but the Minister must be satisfied before he could prescribe anything in any occupational disease, and this meant the collection of data.

STATISTICS IN PSYCHIATRY

At a meeting of the Section of Psychiatry of the Royal Society of Medicine on June 10 Dr L. S. PENROSE, Galton Professor of Eugenics, University College, London, and lately Director of Psychiatric Research, Ontario, gave a paper on the importance of statistics in psychiatry. The simple accumulation of accurate figures concerning the ages of patients and their length of stay in hospital, said Prof. Penrose, was of great value in understanding the scope of psychiatric problems. It was surprising how little use had been made in the scientific study of psychiatry of the simple actuarial material relating to mental illness. Reports of the Board of Control forty or fifty years ago were full of interesting information about the ages of patients admitted to institutions, but presumably this was thought valueless and had been dropped.

The elementary accountability of numbers of patients under hospital care or under treatment at clinics was of great sociological as well as clinical interest. It was common knowledge that only a small proportion of mentally ill or defective persons in a community were actually certified, the proportion depending upon the degree of development of the mental health services. On comparing statistics of all countries from which figures were available, he had come to the conclusion that the amount of attention paid to mental health was inversely proportional to the amount of serious crime. Very roughly, two beds in a mental hospital made one prison cell unnecessary. As prisons cost twice as much as mental hospitals for each inmate, there was approximate economic equivalence, but the social advantage was presumably with the hospital beds. In mental deficiency much could be learned if the age group and intelligence distribution of institutional cases were known. At a guess probably one third of all idiots were under institutional care, one sixth of all imbeciles, but only one-twentieth of all feeble minded, and of borderline cases only a small fraction. Some very marked selective mechanism determined just which cases should be cared for and which left in the community. Families in poor circumstances contributed an undue proportion of institutional cases. Patients with behaviour disorders added to defect were also concentrated in the institutional group.

Among the mentally ill one deduction from statistical data was that the longer a patient stayed in hospital the more likely was he to be a schizophrenic even if that was not the original diagnosis. Schizophrenia, like mental defect, was more severe in males than in females as shown by its earlier onset in the male sex. With affective psychoses the relationship was probably reversed: the female cases, at least those of early onset, being more abundant.

The use of statistics in estimating the effects of toxins, drugs, or remedies had reached a considerable level of accuracy in animal experiments but in medical practice the problem of finding adequate control populations often prevented reliable conclusions. It was possible with good statistical records to find out the chances that a patient first admitted at any given age would be found on the books of a mental hospital at any subsequent point of time. Tables which he prepared in Ontario indicated clearly that fairly good results were obtained after three years by shock therapy in psychosis of late onset, but no appreciable effect was obtained by all the vast amount of work (insulin and convulsion therapy) done on cases of early onset, the majority of which were diagnosed as schizophrenia. He

was aware that many careful observers considered the results unsound and too pessimistic, but he was inclined to think they gave a very fair picture.

Biometric Techniques

Prof. Penrose then turned to an elaborate discussion of biometric techniques. Knowledge of ordinary statistical practice, he said, was very helpful in guarding against elementary errors and in establishing significance or otherwise of metrical deviations from the normal found in mentally ill subjects. Some difficulties arose because the range of variation might be much more marked in abnormal than in normal groups. The increased variance between groups of abnormal subjects as compared with normals was well known. Furthermore, abnormal reactions in themselves might be characterized by either too much or too little variety (i.e. scatter or stereotypy). He described the advantages of the discriminative approach between normal and abnormal reaction as compared with the much more fashionable typological approach. From the point of view of research it was always advisable to proceed from the known to the unknown and thus starting with known differences—as for example between the sexes, between normals and neurotics, or between different types of diseases—the discriminating qualities extracted from these known types could be applied to unknown conditions.

In discussing different types of tests and their outcome he mentioned one result which was suggestive and rather surprising—namely, that male schizophrenics unquestionably tended to give the feminine type of profile or pattern. It appeared also that female schizophrenics were on the average super-female and not, as might have been supposed on the basis of certain other work, intersexual. It seemed that schizophrenics were fundamentally too feminine, or, looked at in another way, many cases of relatively early onset had an intersexual, and those of late onset a supersexual tendency.

In conclusion Prof. Penrose spoke briefly on the elucidation of the genetic background of psychiatric phenomena. Diseases due to rare recessive genes could be detected by finding an increased consanguinity rate in the parents. Among mentally defective patients the incidence of consanguinity in parents was particularly illuminating and indicated that some types of cerebral palsy and microcephaly were due to single recessive genes. The problems of defining clinical entities were better solved by familial investigations than by factor analysis in random samples because only by familial study could factors due to genes be identified. Moreover, combined clinical and genetical observations could reveal the existence of new clinical entities. If the psychoses were in fact made up of a set of separate illnesses each purely genetically determined, there should be no more overlap in families than that due to random expectation. Actually manic depressive and schizophrenic types did overlap in family histories rather more than would be expected if they were quite separate genetical entities.

TREATMENT OF TUBERCULOSIS

A clinical meeting of the Medical Society of the I.C.C. Service was held at Colindale Hospital on June 5. Mr. CILLIAN in opening a discussion on tuberculous empyema pointed out that in the days before penicillin, if such an empyema were secondarily infected a thoracoplasty, though a risky procedure, had often to be carried out. Now repeated aspiration and instillation of penicillin frequently resulted in clearing up the secondary infection completely, with great improvement to the health of the patient, thus minimizing the risk of thoracoplasty if surgical operation were necessary at all. It was important to aspirate high up in the rilla in order to avoid formation of a sinus. Dr. W. F. RICHARDS remarked that there was a danger in continuing the treatment with penicillin and aspiration in mixed infections for too long as many of these cases had a bronchopleural fistula.

Mr. E. T. BAILEY said that the treatment of bony lesions had to be dependent on the general condition of the patient and advised removal of sequestra as soon as the condition of the patient permitted. In order to lighten the work of the nurses in the orthopaedic wards he had adapted the Hex Gloves specially bed for treating cases of spinal and sternal tuberculosis. The

had not found it very satisfactory for female patients owing to the difficulty of micturition. Mr JAMES CARVER said that he had shown several cases of tuberculous epididymitis on whom he had done an epididymectomy, demonstrating that it was possible to get excellent healing and very seldom necessary to remove the testis at all. The psychical trauma resulting from removal of the testis was such that every effort should be made to avoid it. If the testis were involved slightly it might be curetted and the cavity treated with pure carbolic. There was no danger in cystoscopy in these cases nor in retrograde pyelography if necessary in renal tuberculosis.

Dr HURFORD said that before the war he had done a five year follow up on 85 cases of thoracoplasty and found 65% well and working. The best results were achieved by combined operations and sanatorium treatment both before and after the surgical intervention. Dr SMITH pleaded for the use of the laryngeal swab on patients who were apparently sputum negative. In a series of 100 such cases 42 had positive laryngeal swabs. Dr SNELL stressed the importance of bed rest. He had had very good results from strict bed rest even for a year. The difficulty of carrying out bed rest strictly was much lessened if it was accepted as part of the routine of the hospital.

Correspondence

Physical Therapy of Mental Disorder

SIR—There has been so much irrational talk in this controversy that perhaps one may attempt to clarify a few points logically. In the first place a mental illness must either be organic or non organic or a mixture of the two. We will disregard the last as it would only confuse matters. By organic we mean cases due to syphilis, alcohol, trauma, vitamin B deficiency, etc. By non organic cases of depression, mania, paranoia, schizophrenia, and the neuroses. Organic cases obviously cannot benefit by electrical treatment or leucotomy. To turn to the non organic cases. The causes of these are still obscure but an important aetiological factor is an abnormal life situation. This must be tackled. If psychotherapy is applied without this the aetiological factor continues to work and negatives all the results. The question arises, are there really any "non organic" cases? This is a most difficult question to answer but possibly there are not. But here we are still hindered by the nineteenth century notion that the mind is a function of the brain, whereas in reality it is related to the entire body.

The statement is often made that ECT is painless, that it results in immediate unconsciousness. This I am quite sure is not the case. That the experience cannot always be remembered is I believe, due to very strong unconscious repression, but it is none the less real, or else how can it be explained that nearly all patients have an intense and growing dislike of the treatment, so that I have known patients who have had to be dragged to the place of execution by four or five nurses? It is also known from cardiazol treatment, where the interval between the moment of insult and the subsequent fit is longer, that terrible experiences were undergone. One of the results of a whole series of powerful inhibitions accompanied by organic losses of memory is to render the case inaccessible to psychotherapy.

The misleading argument is often produced that if the patient is not submitted to these violent procedures he will become a 'chronic mental hospital patient'. We shall have to examine the implications of this expression. The chronic mental patient is a product of the present type of mental hospital. The sort of treatment meted out in these "prison barracks" is often sufficient to drive a perfectly balanced person insane. To take a minor example a patient who is apt to be rather mischievous was treated by the male nurses by forcibly replacing him on a chair every time he attempted to rise from it. When I first saw this patient this had been going on for about ten years. Is it surprising that he was demented? And far worse things than this occur. Psychiatry has to become a social science and develop a social conscience, and this in more ways than one. In every case of a non-organic psychosis or psychoneurosis there is the family of the patient to consider. If this is not taken into account treatment may very easily be applied to the wrong person.

To take two examples coming to out patient clinics. A boy of 17 was brought to this clinic by his father because he thought he took too much interest in the other sex. The father was the most extraordinary prudish old woman of a man I have ever seen, the boy, we agree, was quite normal. Now are we going to take the boy into a mental hospital and give him a course of electrical treatment? He probably will develop schizophrenic symptoms in the next few years living with such a father, and prophylaxis might be considered better than cure.

Another case—a woman of 30 who showed symptoms of withdrawal of interest in life. She was slightly mentally deficient, and her mother had literally never let her go out of her sight, even into the next room. She was quite lost and terribly upset when the psychiatrist wanted to see her without her mother. I have chosen cases where the family factor is obvious, but I believe it is present in all non organic cases, although it may be most subtly hidden and disguised by the relatives.

At present I have a female patient whose personality has been totally suppressed by her mother—a most dominating personality who uses subtle weapons of "ill health" and "affection" in order to maintain her hold on the family. This patient would probably be labelled as a case of depression and treated by the enthusiasts as a very suitable case for ECT. She would appear to improve and return to her mother, who would gain an even stronger hold by suitable references to her "disgrace" in being taken into a mental hospital. After a time all the symptoms would return. A further course of ECT would be required, and so it goes on until a day would come when the parents would be summoned to the medical superintendent's office and solemnly informed that unless a leucotomy was performed their daughter would become a chronic incurable inmate. They would agree to the operation, and she would be returned to them in a semi infantile condition. The mother is delighted—the daughter cannot possibly leave home now. She will need all her loving attention for the rest of her life. Such things, really happen, I could multiply them indefinitely from my own experience.

The great majority of such psychoses start in adolescence, usually at the age when the young man or woman should leave home and become independent. If we can rescue him from his parents and transfer him to a happy and healthy social circle we can always cure him with the aid of psychotherapy and re education. The great need is for hostels for such cases run by the right sort of people who can create a happy social environment and who have had suitable psychological training. That is one reason why psychiatry must become a social science. It is a tragedy that those who sincerely desire to help the mentally afflicted should be attempting to do this by converting the curable non organic case into an incurable organic one for anybody who has had several courses of ECT or a leucotomy is actually a case of traumatic psychosis. It may be easier to handle such a traumatic case than to deal with a complex life situation with difficult psychological factors, but this sort of traumatic case is really incurable, and they are mounting up. An enormous amount of unnecessary mental and physical distress is being created by the popularity of these methods—their quick showy results which are not cures at all. Future generations of doctors will be as much appalled by them as we are now by the former treatment of cholera by blood letting and purging.

To sum up (1) The mental hospitals need to be pulled down and replaced by social centres, hostels, and a boarding out system for all but the most acute cases. The co operation of factories run for disabled persons can be of the greatest value. (2) Acute cases should be treated by rational physical therapy, not brain damage, in a general hospital. (3) The total life situation of the patient must be tackled, otherwise psychotherapy may be ineffective. (4) There is need for research in psychosomatic medicine. (5) Improved general education of psychiatrists so that they can see through the fallacy of converting every case of doubtful aetiology into a traumatic psychosis by means of ECT or leucotomy—I am etc.

London NW 11

T GLADSTONE

SIR—The controversy regarding the merits of psychological and shock treatment seems to be the result of confusion. Dr D W Winnicott (May 17, p 688) upholds psychotherapy and condemns shock treatment. Naturally he does so, since his time is devoted to the treatment of neurosis, and presumably he sees few if any psychotics. Psychotherapy is the treatment of choice for neurosis and in experienced hands produces excellent results, so he sees no good in electrical or other methods of cure. Similarly all the irate psychiatrists who written such virulent letters against Dr Winnicott are those who treat psychotics. Now admittedly psychotherapy is a satisfactory weapon against the psychoses, and in proper

the shock type (ECT or insulin) of therapy does produce results whether Dr Winnicott wishes to believe it or not.

My personal complaint is that this schism tends to split psychiatry into two camps. Surely the proper training should consist in a basis of psychotherapy for the neuroses and a knowledge of electrical and insulin treatment for those who need it. Unfortunately there are many who, in their ignorance, have come to despise psychotherapy and delight in their shining machines and glittering syringes. In the same way the more conservative of the older psychiatrists refuse to countenance the occasion for good in the new ways and curse the young for whoring after strange gods. It seems to me that the simple secret of cure is the ability to diagnose the psychiatric condition and the broad mindedness to use the right method, whether shock or psychological. Such success as has come my way has come from this.

Now may I offer a criticism of those who use shock treatments? First, they do not cure such illnesses as homosexuality, fetishisms, hysteria and simple neuroses yet I have seen them uselessly applied. Secondly, only this week a woman came to me who feared to have ECT because she had been hustled into a side room all ready for the machine as soon as the preceding patient had been whipped off. Unfortunately she heard the epileptic cry, and this unearthly sound haunted her so that she feared to have further shocks. I have seen similar patients. It is a piece of unnecessary cruelty to allow such a thing to happen whether we believe that mental illness is the result of a 'subacutely or chronically diseased physical organ called cerebrum' or not. Lastly, may I suggest that leucotomy should be reserved as a forlorn hope for those who have failed to respond to ECT, insulin and perhaps prolonged narcosis? It has a significant death rate, and severe injury to the personality may result even if no intellectual damage does result.

Let it be thought that I am hostile to organic forms of treatment may I record a case which passed through my hands many years ago and which suggests that there may be undreamed of forms of treatment? This was a middle-aged woman with mitral disease. She was so grossly hallucinated that she kept the ward echoing with her shouts of abuse. Her days were hell and her nights a torment. Then one day she developed an infarct in the left side of her brain with a resulting right hemiplegia and motor aphasia. The "voices" stopped instantly as if disconnected. When she was recovered enough to be able to express herself she said that it had been truly magical. Perhaps one day a surgeon will be able to repeat such magic at will—but we shall still need psychotherapists for the neurotics—I am, etc.

London W 1

CLIFFORD ALLEN

SIR—Psychiatrists in general and all those interested in the empirical aspect of psychiatric research, particularly on the therapeutic side, will view with some misgiving the prominence afforded to the criticisms of the physical treatments of mental disease outlined by Dr D W Winnicott (May 17, p 688). If my memory is correct, Dr Winnicott has already voiced similar criticisms in the correspondence section of the *British Medical Journal* where viewpoints do not lose their purely personal touch. When, however, these personal opinions are promoted to the importance of a special article, they tend to assume the imprimatur of authority and are consequently liable to be accepted as unimpeachable expert opinion based on extended and specialized experience. They must, on this interpretation, create widespread misconception among non-psychiatric medical colleagues particularly when they are of an exclusively destructive nature as in this case.

Dr Winnicott's opinions, apparently given originally to the medical section of the British Psychological Society would appear to constitute, in a rather defensive fashion, the viewpoint and attitude of the purely psychological school of thought towards mental disease, as represented actively by the psychoanalysts. To the latter any encroachment, with a tendency to monopolopoly, by the physical therapists must appear in the light of rank heresy and be denounced as "empirical magic". Every experienced psychiatrist admits the necessity of recognizing both psychological and physical factors in mental disease and wisely combines both in his therapeutic approach. The American authority, Dr A P Noyes emphasizes this point in his *Modern Clinical Psychiatry* as follows

"No one formulation, whether it be chemical, physiological, neurological or psychological, can explain all the phenomena observed in those personality disorders that we call mental disease. We must remember that much of our talk about the unconscious, about organic lesions and about disturbed chemistry is as yet hypothetical. In psychiatry we deal with the socially conditioned biopsychic life of the individual, and the biopsychic life, it is obvious is subject to an incalculable variety of influences."

ECT, which has been mainly attacked by Dr Winnicott and rather flippantly, on the grounds that psychiatrists do not use it on themselves may not in many cases, effect a cure *per se* and is generally followed up with a combination of psychotherapy and occupational therapy, as here in Killarney Mental Hospital. All three create a reinforcing effect in the therapeutic adjustment of both the psychic and physical elements of the disorder under treatment. In actual fact, ECT effects a very high percentage of recoveries in the true uncomplicated depressive psychoses particularly the involutional types. The high percentage rate of recovery is such that the criticism of Dr Winnicott even though admittedly based on "personal prejudice" will not cause any undue anxiety among practising psychiatrists. Further the efficacy of ECT in the case of all confusional psychoses of toxic origin whether puerperal or otherwise, is of such a nature as to be regarded as specific.

Dr Winnicott's reference to "organized paranoia" would suggest on his part, some confusion in nomenclature as well as practice. Quite obviously, from his ensuing remarks, he is confusing the paranoia with the paranoid form of schizophrenia, and his suggestion of the indiscriminate use of ECT for this latter disease is entirely contrary to recent practice. It is now generally admitted that unmodified ECT for any form of schizophrenia does not effect a cure even in the acute cases. This is our experience in this hospital though there have been very encouraging results in the administration of ECT following thyroxine premedication in acute and recent cases. In one such case, where a full course of deep insulin therapy had been a failure, there was a very successful result in the modified form of ECT described.

All treatments, whether physical or psychological, will be judged on the following considerations: (a) good results achieved, (b) the permanency of these results, and (c) absence of injurious effects whether immediate or residual. (a) The results in the conditions already outlined cannot be questioned on any extended experience. (b) Present experience goes to show that there is a very high degree of permanency in the results achieved for the conditions mentioned above. Even in the very small number of receding cases hospitalization is reduced to a very considerable extent as against control cases. (c) There are no immediate ill-effects that would contraindicate ECT, and the alleged brain damage has not been borne out in the vast number of cases that have been submitted for the treatment. It is on these three grounds that ECT has been accepted as a very definite therapeutic advance in psychiatry, even Dr Winnicott admits rather pointlessly, "I have no hope that these arguments will make any sudden difference to the now established practice of psychiatry."

There are many other points in Dr Winnicott's article as absurd as they are flippant that do not merit recognition much less contradiction. There is however, reference to mental hospital management in the penultimate paragraph of his article which is entirely contrary to fact. Probably in no form of nursing are the qualities of forbearance, patience and understanding so necessary and still so generally exercised as in psychiatry and to suggest that it is permeated with hatred and cruelty exists a very objectionable reflection on modern mental nursing. This unfounded charge is no less absurd than the "sympathetic" consideration expressed for the doctors and nurses whose protection from developing "emotional instability" in the course of their work may be seriously threatened by the "abolition of shock therapy". Does there exist a rational being who is convinced of either the validity or the sanity of such trivial nonsense? Dr Winnicott apparently thinks there does—I am, etc.

EDMON N M O'SULLIVAN

Tuberculosis and Diabetes Mellitus

SIR—I should like to associate myself with Dr Wilfrid Oakley's plea (May 31, p 780) for sanatoria where efficient management of diabetes could be given to diabetics being treated for pulmonary tuberculosis. The tuberculous diabetic does not often receive adequate treatment for both his diseases and it is therefore not surprising that many of these patients die badly. It is essential that both diseases receive proper consideration, and until special centres are created to ensure this

correct management of both maladies the results will not give hope and encouragement to sufferers or their medical advisers.

The tuberculosis service in this country may have reached as high a peak of perfection as it has ever attained since its inauguration but this will hardly avail the diabetic unless his metabolic disturbance be at the same time under expert supervision. Experience has shown that good treatment of the pulmonary disease with inadequate supervision of the diabetes is as harmful as poor treatment of the phthisis with proper control of the diabetes. It goes without saying that bad treatment of both conditions is inevitably disastrous. The truth is that in many instances the tuberculous diabetic is uncared for according to the best medical standards, and the evil effects of this are brought to our notice in the published results of treatment.

At the few clinics where adequate control of both diseases has been enforced from the beginning the results have indicated that the outlook for the diabetic who develops phthisis hardly differs from that of the non diabetic. Figures published from sanatoria in the past have led to false conclusions as to the seriousness of the combination of these two diseases, the bad results obtained were probably due to inadequate control of both conditions according to modern therapeutic standards. Unfortunately this fact has not been fully realized, with the result that the tuberculous diabetic has acquired a stigma of hopelessness based on mismanagement of his diseases.

Publication of the new version of Section I of the Appendix to Memorandum 37/T (Revised), which has been accepted by the Ministry of Health (Supplement May 31, p 111), raises important considerations concerning the tuberculous diabetic. In the section on the classification of patients suffering from tuberculosis, it is stated that "all cases with grave complications, whether they are tuberculous or not should be classified in this group [group B3] (e.g. diabetes, tuberculosis of intestine or larynx)". My first objection to this new classification is that it places the diabetic whose disease is complicated by a small pulmonary lesion in the same category as the patient with advanced bilateral fibro-cavernous disease. Secondly, the presence of diabetes is looked upon in the same light as tuberculous enteritis or laryngitis. Here, surely, a gross injustice is done to the diabetic. Whereas the onset of tuberculous enteritis in most cases heralds a fatal issue, the outlook for the tuberculous diabetic, as emphasized already, is never as serious as this unless by virtue of the extent of his pulmonary disease. The combination of diabetes and tuberculosis should never be regarded as the equivalent of hopeless and irrecoverable disease.

Apart from the objections on medical grounds to placing tuberculous diabetics in the class B3 one can imagine many other disadvantages that such a patient may suffer owing to his consideration in this group. B3 cases have always been regarded as suffering from advanced pulmonary disease, so that there has been no urgency in considering their admission to sanatoria for treatment. They may be left at home, if conditions allow, or they may be admitted to homes or hospitals for advanced cases. It would be most unfortunate if tuberculosis officers should be led, after reading the new classification, to treat their tuberculous diabetics in a like manner. The development of phthisis as a complication of diabetes should be looked upon as a medical emergency, requiring prompt treatment for both conditions. An unnecessarily long wait for admission can only mean advance of the pulmonary disease together with inadequate control of the diabetes and a poor outlook for the patient, accordingly such patients warrant priority on the waiting lists. Finally are the benefits of the maintenance grants from the Treasury (Memo 266/T) to be withheld from tuberculous diabetics under the new scheme of classification?

The diabetic surely has to suffer enough already on account of his unfortunate affliction without having additional difficulties put in his way which are based merely on prejudice and receive no support from properly instituted clinical studies. It is to be most earnestly hoped that further consideration may be given to the amended Section I wherein diabetics are included in class B3 and that special units will soon be established for the treatment of tuberculous diabetics—I am, etc.,

M. Idstone Kent

GEORGE R. W. N. LUNTZ

Classification of Tuberculous Patients

SIR—Dr H. E. Stevens's letter (May 31, p 782) draws attention to a deficiency in the new classification of tuberculosis terms recently adopted by the Ministry of Health. The object of adopting the new classification is not stated but presumably it is mainly to secure increased accuracy of returns through clarification of the headings used in compiling them. My own belief

is that this object will not be attained by the present proposals, and if other tuberculosis workers feel the same they might consider whether it is worth their while to ask for a re-examination of the scheme now put forward.

The following are some of the grounds on which I base my opinion.

(1) The replacement of the self explanatory terms "minus" and "plus" by A and B is to me a retrograde step, and is bound to lead to mistakes in classification owing to the absence of any apparent relation of the letters A and B with either positive or negative cases.

(2) The definitions of respiratory and non respiratory tuberculosis are not free from criticism. One expects these definitions to be helpful to the extent that few, if any, occasions will arise when it will be impossible to classify a patient by their use. But such occasions are bound to happen when no provision is made in the definitions for including conditions other than those specified—for example, endo bronchial tuberculosis. The difficulty would be overcome by substituting the words 'a respiratory case includes' for the words 'a respiratory case should be'.

(3) A 'combined' case—e.g., with pulmonary and glandular tuberculosis—is classified as a pulmonary case, as at present. But if such a patient is found to have tubercle bacilli in his excised glands he will be classified as B, giving the impression that he is infectious in the same degree as a patient who is discharging tubercle bacilli in his sputum. The definition of an infectious pulmonary case is incomplete, like the general definition of a pulmonary case. The finding of tubercle bacilli should be more definitely related to the pulmonary lesion by specifying the situations where the bacilli will be regarded as evidence of their pulmonary origin.

(4) The definition of a class B case suffers from the further defect that it makes no provision for reclassifying a recovered case who comes on the dispensary register again after a period of years. According to the literal application of the wording a person who had tuberculous cervical glands in childhood with tubercle bacilli in the pus from the glands, and who comes on the register with any tuberculous condition 20 years later, is to be called a B case. For the purposes of compiling uniform statistics this procedure may be very desirable but the statistics themselves can hardly be helpful. I submit that a definition of a "return" or "restored" case is required, and that the classification of such a case should be based on the current findings and not on the bacteriological results obtained many years previously.

(5) The subsections of paragraph III of the memorandum are inconsistent. Subsection (2) states that respiratory A's and B's should be subdivided, subsection (3) states that they should be further subdivided. Yet there is only one basis of subdivision described—viz., into groups 1, 2, and 3. The meaning is clear enough, but the wording is confusing.

(6) The definition of "quiescent" does not make any allowance for variations in bacteriological control by different observers. Some will rely on repeated slide examinations, some will prefer culture or inoculation methods. But, according to the definition, unless three consecutive monthly slides are negative, the case does not fulfil the criteria required for quiescence. Moreover the definition does not take account of the fact that a patient may not be able to produce sputum when required at monthly intervals, and it seems clear that it cannot be strictly observed as it stands at present.

(7) The classification 'arrested' does not seem to serve any useful purpose. In practice it is never used to describe any patient, and rather than set down details for its interpretation I consider it should be abolished.

(8) Does the definition of a "recovered" case apply only to pulmonary patients? If it is intended to apply to non pulmonary patients also, then it should be stated, as at present a non pulmonary case can be written off as "recovered" after three years.

(9) Regarding the definition of "active case," I consider it unfortunate that, by implication, all patients not positive within the preceding three months may be taken to be classifiable as not active—i.e., quiescent. I am sure this is not the intention but the wording is not so helpful as it might be.

(10) The use of the word "stationary" to denote a case in which the patient remains *in statu quo* appears unscientific unnecessary for if a patient was "quiescent" at the

The Twenty-Lozenge Pack

Penicillin Lozenges A & H are issued in glass tubes to prevent inactivation of the penicillin by atmospheric moisture

The number of lozenges contained in the tube (TWENTY) provides the most suitable package to meet the needs of individual treatment prescribed by the physician. Not only does it tend to eliminate waste but it assures the prescriber that the lozenges will not have time to become inactivated by exposure to a moist atmosphere before the prescribed treatment is completed

Penicillin Lozenges A & H are indicated for the effective local treatment of bucco-pharyngeal infections

In tubes of 20 Lozenges

3 vitamins without reserve

Because vitamin B₁, vitamin C and nicotinic acid are water-soluble factors the body is unable to maintain supplies 'in reserve'. Even a brief interruption of the normal food intake results in a combined deficiency of these vitamins, a deficiency which may be manifested in the debility, fatigue and generally 'run down' states often seen in general practice.

Nicorbin Tablets combine these water-soluble vitamins in therapeutic amounts providing a certain and convenient means of ensuring an adequate intake. Given thrice daily, Nicorbin Tablets exert a powerful tonic influence and should be prescribed in conjunction with Adevalin (vitamins A and D) when a general raising of the nutritional level is desired.

GLAXO

Composition: each Nicorbin tablet contains
Aneurine hydrochloride (vitamin B₁) 1 mg
ascorbic acid (vitamin C) 25 mg
nicotinic acid (P.P. factor) 10 mg

operative dietary

In pre- and post-operative cases, where the general state of nutrition gives cause for anxiety, 'Pronutrin' will be found a useful food. It is a natural antacid and provides the necessary nitrogen for tissue-building and repair, in a form the body can most readily absorb. 'Pronutrin' is an enzymic digest of casein. The casein is broken down into smaller units of amino acids and the simpler polypeptides. 'Pronutrin' is a free-flowing powder, soluble in water. It may be given in hot, cold or iced water, either alone or combined with meat extract or tomato puree, or it may be stirred into milk or soups. A booklet giving fuller details will gladly be sent on request.

DEPRESSION

The following instances of simple depression are familiar to every physician:

- 1 Depression following acute infectious diseases, typically influenza
- 2 Post-partum and post-operative depression
- 3 Depression accompanying the menopause in women and the involutional period in men
- 4 Depression associated with menstrual dysfunction
- 5 Reactive depression precipitated by an external problem situation which the patient cannot resolve, tolerate or ignore

In all such cases 'Benzedrine' therapy may be expected to help reawaken mental alertness and optimism and to restore the savour and zest of life

etc.

of the "stationary" period, he may continue to be described as quiescent rather than as stationary.

(11) Among the definitions not mentioned is the Ministry's own term "inactive" as used in the classification of mass radiography findings. I think it a pity that the opportunity has not been taken to make clear the implications of the use of this term.

(12) The inclusion of directions for the medical assessment of patients suffering from pleurisy has the appearance of an intrusion in a document dealing with the classification of patients suffering from tuberculosis. I consider that the direction to regard pleurisy as tuberculous unless proved otherwise is inconsistent with the facts (a) that less than half of the patients who suffer from pleural effusion ultimately develop pulmonary tuberculosis, and (b) that pleural effusion is frequently part of a primary tuberculous process. The requirement that cases of pleural effusion should be regarded, and presumably notified as tuberculous will have repercussions in the matter of the notification of primary tuberculosis in general.

(13) The new Non-Respiratory classification will not show the part affected. The old classification was in four groups: (1) bones and joints, (2) abdominal, (3) other organs, (4) peripheral glands. It is desirable that the subdivisions of the old classification be incorporated in the new groupings.

(14) If the old method of classification is to be amended, let us make sure it is soundly based, because it will involve the reclassification of all the cases on the dispensary registers so as to afford comparison with previous years.

In issuing their memorandum the Ministry have no doubt acted on the advice of the Joint Tuberculosis Council, but it is regrettable that no opportunity was given to tuberculosis workers in general to express an opinion before the recommendations were forwarded to the Ministry—I am, etc.,

Artificial Insemination

SIR—There can be few subjects which call forth more emotional (as opposed to intellectual) judgments than AID. The letters from Dr Eustace Chesser (May 24, p. 738) and Dr Farquhar Murray (June 7, p. 826) are cases in point. The latter is so carried away by his disgust of the whole procedure that he does not present the facts quite as they are. The only donors I have ever met are unselfish and intelligent men who do not sell or barter their spermatozoa but who agree to give them, as they would blood for transfusion to help those in need—i.e., equally unselfish and intelligent couples who, because of the husband's complete sterility, have been deprived of begetting, bearing, and rearing the children they earnestly desire, more often than not through no fault of their own. Dr Chesser, on his part, paints a somewhat lurid picture of the formidable hazards surrounding those rash enough to indulge in AID. He says he has abandoned the practice but omits the facts and figures that induced him to do so. For example he does not tell us how many cases he has dealt with by AID, nor how old the resulting children are, neither does he give any indication as to what proportion of his cases has ended in psychological disaster; he seems to infer that there are few, if any, good results. Possibly facts and figures are lacking and he has arrived at his conclusions on theoretical considerations only. His letter would have carried more conviction had he also painted the other half of the picture, which undoubtedly exists.

The marriage in danger of being wrecked by the smouldering resentment of the maternally inclined woman against her sterile mate and the profound sense of failure and regret which must be felt by any but the most insensitive husband—in my experience this is the situation which, unless resolved, besets two people with "formidable hazards." There are of course a number of ways out, and it lies within the doctor's sphere to try honestly and without prejudice or emotional bias to help such couples, should they consult him, to find their particular solution. The possibilities are to be sufficient unto themselves and to sublimate in various directions, to part and start afresh, to adopt, or, finally, to secure a child or children by AID. A small proportion may after careful thought choose this last; the husband conscious of his wife's strong desire to bear a child and preferring to fend for one that is at least hers rather than

one that comes of neither of them. His sense of inferiority and of guilt tends to remain while the cradle is empty and is not, in my experience, replaced by jealousy of the child but by the great tenderness towards it and towards a wife who has, in the sense that matters to him, kept faith, while she in her turn feels a lasting gratitude towards her husband for his generosity in allowing AID. So far I have not met the unhappy situation Dr Chesser so vividly depicts, quite possibly I have not dealt with so many cases as he has and my experience of the outcome of AID is therefore more limited than his. His warning will ensure a still more careful selection of cases. Finally I would suggest that it is early days to pass sweeping judgments in either direction. It is well to bear in mind that the demand for AID, no less than for control of fertility, has come from the lay public. It is of prime importance that doctors should think about and weigh these things in the light of their special knowledge and experience, setting aside in so far as they can or at any rate recognizing, their own particular emotional bias in the matter—I am, etc.,

MARGARET HADLEY JACKSON

Acid Drinks and Sulphonamide Therapy

SIR—It is pertinent to ask the advocates of freely drinking of the fruit juice beverages by what processes the vegetable acids or their salts, citrates, etc., come to be passed off in urine so as not to increase its acidity. The acid part gets oxidized and the other parts also get oxidized, CO_2 and KHO or H_2O being end results. The amount of oxygen required to achieve this end is not negligible. The citric acid molecule for its change must have added to it 9 molecules of oxygen, its molecular weight, given as 210.1 requires of oxygen 9×16 , or 144. Where and how is the citrate to get it?

The bodily state in each case must be considered in regard to this important matter. It is of course the doctor's privilege to deal with this. The sulphonamides themselves do make some demands upon the respiratory functions, all of whose details including of course the RBC's may be affected and in many cases the disease may be one directly affecting respiration. My colleagues in the eye specialty need not be told that prolonged or drastic degradation of oxygen supply and possibly the presentation of un- or imperfectly de-toxicated products is of importance to the retina and the lens. Others should be told.

The drinking of large quantities of water may be rather relished as an uncommon item, and if taken cold or even chilled or iced may, if thought advisable, send more of it to the kidney rather than the skin or lung for elimination. A lump of sugar in it used to be liked and would be welcome as a reward. Lemon and orange juice drinks are taken far too little diluted in many cases, and it might be wise to prescribe the actual dilution considered safe as well as the total daily allowance. In the sick there are limits to the capacity for dealing with excess in H_2O and CO_2 , methemoglobin and the discolor products and those due to our drugs. The wisdom of the ancients is still apropos: *Est modus in rebus! sunt certi denique fines Quos ultra curaque nequit consistere rectum*—I am, etc.

Glasgow

ED J PRIMROSE

Nicotinic Acid Tolerance Test

SIR—I read Drs P Ellinger and S W Hardwick's excellent paper (May 17, p. 672) and Capt A Erdős's letter (June 7, p. 822) with great interest. Both contributions suggest the intimate relationship of the functional state of the liver parenchyma to nicotinic acid metabolism, a problem elucidated mainly through the systematic work of Ellinger and collaborators in recent years. At the beginning of the war I had the opportunity of studying the physiology of the small intestine. I was able to submit evidence for the assumption that the gradient of absorption in the small intestine is to a great extent maintained by the catalysts of the intracellular respiratory enzyme systems. It is known that at least 3 water-soluble vitamins—thiamine, riboflavin, and nicotinic acid—are closely related to these catalysts and it could be tentatively suggested that a deficiency in these vitamins and a liver "dysfunction" may be instrumental in the production of the sprue syndrome (Leitner, 1942). During subsequent years injections of crude liver extract (containing most of these enzymes) became a routine in the treatment of sprue.

Cap' Erdős's interesting experience that acute spruce symptoms were provoked by giving 1,800 mg nicotinic acid daily for 5 days and that the symptoms were quickly cleared up by subsequent massive doses of riboflavin is a case in point. It also presents an interesting example of an imbalance of the vitamin B equilibrium. During recent years attention has been directed repeatedly to the importance of the interrelationship among the various factors of the B group of vitamins. It could be demonstrated that subclinical latent deficiencies might become manifest after giving large doses of one single crystalline vitamin of the group (Richards 1945, Leiter, 1945, 1946, 1947). Another interesting feature of Cap' Erdős's case is that spruce could be produced experimentally by disturbing the vitamin B equilibrium—a fact which to my knowledge has not been reported before. For this reason it would be of great interest to have a more detailed description of the symptoms in his case.

Although a considerable number of minor symptoms due to the imbalance of vitamin B factors are frequently encountered major disturbances appear to be comparatively rare. I should therefore be greatly interested to learn of any such cases—I am etc

Folic Acid

SIR—Dr J G A McSorley (June 14, p 863) evidently misunderstood my letter in the *Journal* of May 24 (p 740). I stated that folic acid 10 mg daily, was given plus a maintenance dose of liver weekly. Although intensive liver therapy was given for three weeks previously, the nervous disability was but slightly improved. After a few days of the combined treatment a marked and steady improvement followed. This improvement has been maintained and is progressing. The patient, a joiner, is able to walk a considerable distance without even the aid of a stick and work for several hours at his bench.

The spastic type of subacute combined degeneration of the cord has, I think, always been regarded as the least responsive to any form of treatment. It was the disappointment following liver therapy alone that made me try folic acid in addition and the result has more than justified the action—I am etc,

Birkenhead

CECIL L FORDE

Hypereosinophil Phase in Allergy

SIR—In my first communication (June 7, p 823) it was shown how blood hypereosinophilia proved to be one of the leading signs, pointing to allergy as a possible causative factor in a case of pruritus and a condition so far not considered as connected with allergy. Scepticism was expressed against this idea when a repeated blood count showed normal figures of 2% eosinophils. The 'allergist' is well aware of quick and transient organic changes in allergic conditions. Swellings, catarrhal signs, local and blood hypereosinophilia come and go as quickly as spasms and are also caused by the parasympathetic irritation which is at the root of allergic signs and symptoms, due to an almost inexhaustible variation of causative factors.

Seen in this light the positive findings appear of diagnostic value whereas the negative are inconclusive, similar to a negative W.R. in syphilis.

Blood hypereosinophilia occurs in experimental anaphylactic shock as an expression of the parasympathetic irritation, together with the other signs of it. Clinically it is known to occur in allergy particularly in bronchial asthma, in parasitic infections such as worms in certain fevers during the "crisis" at the moment before immunity and recovery is setting in—e.g. in Weil's disease (infective spirochaetal jaundice) in scarlet fever and in such conditions as Loeffler's syndrome all now well connected with allergic reaction. Apart from this it is observed in Hodgkin's disease a condition of unknown origin and pathogenesis. Otherwise response to foreign protein is a common factor, and in my opinion the probable cause of hypereosinophilia.

Authors agree that blood hypereosinophilia of 5% or more occurs in 35.55% of the allergic patients. More recently it has become a clinical custom in U.S.A. allergy clinics to do three weekly differential blood counts and to use the average figure obtained as expression of the eosinophil count. I am, however, of the opinion that this is not a suitable method and that any observation of a hypereosinophil blood phase is the characteristic allergic response to parasympathetic irritation which we wish to take into account for our diagnostic considerations in allergic conditions, however transient it may be. Ups and downs in the figures may prove to be of prognostic value or may be due to the effect of therapy but that has still to be established.

Among 100 L.C.C. hospital patients with bronchial asthma examined during a given period I obtained 0.4% of eosinophils (normal figures) in 44% of the patients hypereosinophilia of 5% or more in 56% of them. The blood films were examined in the group laboratories. Among 100 private patients with bronchial asthma examined lately and also chosen at random normal eosinophil counts of 0.4% were observed in only 37% and hypereosinophilia of 5% or more in 63% of the patients. The blood films were examined by myself. The suspicion that this was due to a personal bias of the examiner, was removed when an analysis of the counts revealed that the difference was due to a higher figure of patients with a hypereosinophilia of over 20% eosinophils. Changing figures in the same patient had been observed frequently before in reports and by myself during the course of observation.

Eosinophils per cent	In 100 L.C.C. Hospital Patients	In 100 Private Patients	Average in 200 Private and Hospital Patients
0-4%	In 44%	In 37%	In 40.5%
5-9%	In 36%	In 37%	In 36.5%
10-20%	In 18%	In 19%	In 18.5%
Over 20%	In 2%	In 7%	In 4.5%

All this suggested that the hospital patients, who had been under treatment before I saw them and had mostly been given adrenaline, did not show the high eosinophil counts so frequently because their parasympathetic irritation had been diminished by treatment and the "hypereosinophil blood phase" had been diminished or had disappeared for that reason. A clinical experiment proved this view to be correct. A boy came under private observation with bronchial asthma. A blood film was taken and 7 min (0.45 ml) of adrenaline solution 1:1000 was injected subcutaneously. Ten minutes later another blood film was taken and both were sent to a laboratory. The first blood film before adrenaline showed 13%, the second one after adrenaline 9%, of eosinophils. The asthma attack had subsided, but rhonchi were still present when the second film was taken. In another boy of 14 years with asthma the same experiment showed 9.5% before and 1% of eosinophils after injection of 7 min of adrenaline, when asthma attack and rhonchi had subsided.

The "hypereosinophil blood phase" seems therefore to be the characteristic reaction to "allergic" irritation and to disappear with it. It is of diagnostic value, and preferable to an average estimate of three weekly repeated eosinophil blood counts—I am, etc,

Oxygen Poisoning in Man

SIR—I feel I must answer certain points raised in Sir Leonard Hill's letter (June 21, p 900). I would like to make it clear that, so far as I was concerned, the Admiralty provided the experimental facilities. The financial and other arrangements were not my affair, nor were they made known to me. Even if I had been aware of these arrangements I would not have presumed to acknowledge or discuss such matters, but would have left this to the proper levels. This is an elementary Service procedure which most people will appreciate on personal experience. I am sure that Sir Robert Davis head of a highly progressive and successful industrial concern

ion, has no wish to be represented as a misunderstood back-room genius. He has financed and encouraged an enormous amount of research by eminent physiologists in the past, and the majority of their findings have been published in the appropriate journals. I myself was working under the Admiralty and I make no apologies for my acknowledgements.

With regard to technical points raised:

(1) Mixture breathing apparatus was not employed by midgeet submarine divers, human torpedoes, divers, or frogmen. The types of mixture breathing apparatus used by the 'human mine-sweepers' was a counter-lung apparatus and an entirely new departure. It was developed by the Admiralty Experimental Diving Unit with the invaluable aid of Prof J B S Haldane and Dr H Haldane, who also carried out a large series of experiments.

(2) The details of the attack on the Tirpitz in Sir Leonard's letter are grossly inaccurate. The Admiralty, so far as I know, have not yet released the full technical account.

(3) When oxygen is breathed in a submerged decompression chamber, it is "in the dry," and therefore no symptoms would be expected in the times employed.

(4) When Sir Leonard read my reports to the Admiralty he should have noted that a full series of *mouthpiece and alveolar samples* was carried out and that no accumulation of CO₂ was demonstrated. The editorial pencil removed this detail from the article in this *Journal* owing to space difficulty. I cannot seriously entertain the suggestion that the operational and experimental mouthpiece divers of the recent war were not experienced or stable, nor that their breathing was apprehensive or abnormal.

(5) Behnke's article in which he advances his theory of nitrogen intoxication is to be found in the bibliography of my article. He does not contradict Behnke's postulate, but offers an explanation of its mechanism on theoretical grounds. This remains to be proved or disproved.

Lastly, I would like to emphasize that my admiration of Sir Robert Davis and his organization remains unchanged and that I would greatly regret any friction which might have arisen as a result of Sir Leonard's letter—I am, etc.,

London EC 1

K W DONALD

Leprosy and its Problems

SIR—In the leading article on leprosy (June 7, p 813) you state that of the 2,000,000 lepers in the world 97.5% are Indian or African. The remaining 2.5% is made to cover the lepers in China, Japan, Korea, and the Philippine Islands, to say nothing of the large number in South America.

My own observations, recorded in my book on leprosy in China, put the figure in that country alone at 1,000,000, and I am now convinced that this is an under- rather than an over-estimate. I am afraid that the problem is a good deal larger than you allow for, and as the bulk of the victims in China are of the lowest economic level, the difficulty of supplying the new drugs for treatment is almost insuperable—I am, etc.,

Bedford

JAMES L MAXWELL

Penicillin for Osteomyelitis in Childhood

SIR—We welcome the confirmation (June 21, p 900) from the Royal Hospital for Sick Children, Glasgow, of our experience that excellent results can be obtained in osteomyelitis of children by penicillin plus minimal surgery. This is also in line with the work of Prof Ian Aird, and we believe that workers in another great children's hospital, that of Newcastle, have had similar results. We should be grateful for information from there and elsewhere.

In reply to three points they raise: (1) We did not use incision and primary suture ourselves, but would be very interested in what they consider the indications for it as opposed to aspiration. (2) We think the bone marrow should be left alone. We regard osteomyelitis as being like a cellulitis that is best left untouched in the early stages rather than a condition in which pus under pressure urgently requires relief, as in mastoiditis. (3) They suggest that we should not record cases which we believe to be aborted osteomyelitis. But surely this group is the most important of all, as a perfectly efficient medical profession would see that every case fell into it, instead of diagnosing most of them in the stage of invasion as "rheumatism." Also we would hardly class an abscess, whether originating in the soft tissues or not, as an aborted case.

The letter from Mr J Trueta and Dr M Agerholm (June 21, p 899) is in a different category, and we can hardly accept it

as a genuine attempt to increase medical knowledge. Nearly all medical papers, especially those written by several authors, contain obvious slips, and ours is no exception. In the summary it was said that "surgical treatment was confined to aspiration" without the note needed to bring this into line with the paper proper and the table that this did not apply to five cases rather different from the rest. Those accustomed to medical reading overlook such things, just as in the ordinary way we should not bother to comment on the fact that Mr Trueta, in quoting our figures, substitutes 3 for 31 cases, under two years for under one year, 7% for 10% positive blood cultures, and twelve times for ten times the normal resistance to penicillin. Such minor errors have no effect on the argument.

The next point is more serious. Our paper attempts to summarize a mass of cases, many of the utmost complexity. Months of struggle or long pathological reports have been compressed into a couple of words. We would welcome analysis, and questions on the series if the spirit of them were that of medicine rather than law or politics. But let us analyse the analysis.

(1) It cannot have escaped Mr Trueta's notice that, of the five cases in which surgery other than needling was used, two were infections from intramedullary drips. He must know that in these there would be a skin wound and a superficial cellulitis to start with. They are not, as we point out, really the same as the ordinary haematogenous osteomyelitis at all. Two others were abscesses of the palate, as unsuitable for the primary suture he advocates as for our aspiration. In the fifth one we admit we ought to have explained that the bone was drilled by a junior under a mistaken impression of relapse after three weeks' penicillin treatment, without any effect except an apparent lengthening of the period of healing. The marrow was sterile at operation.

(2) They state some cases "have had considerable bone damage—one after 11 aspirations." This must refer to case 8, in which our statement that there was "much bone destruction and sequestration" obviously refers to the original condition, as it is followed by the words "Now sequestrum not evident. Regeneration." It is difficult to class this as a slip.

(3) They write, giving the suggestion of quoting us: "Complete recovery" includes "erosion of the head of the humerus, now delay in epiphyseal development." We never used the words "complete recovery" but "complete restoration of function," which is something quite different. The word "now" makes it clear that the erosion of the head of the humerus was the original condition, which could not possibly result in anything but some delay in epiphyseal development.

(4) They translate our statement that "movement was encouraged" into an advocacy of weight-bearing on bones that may not be able to stand it. To weight a homily against this rash practice they refer to the fracture in case 14 without mentioning that the patient was nine months old, and the fracture occurred before treatment started.

(5) They exclude two of our cases with one aspiration and negative local cultures, since they "presume" no pus was obtained. Yet pus was aspirated some days after penicillin treatment was commenced.

(6) They explain at length why aspiration should not work, without mentioning the undoubted fact that we and others have found that it does.

(7) They ignore the fact that in fourteen of our cases we have been able to dispense with surgery altogether.

(8) They refuse to consider the cases of osteomyelitis which we think the most serious—those in which the bone infection communicates with a joint—as osteomyelitis at all. Their pathology, according to which the infection invades the marrow from the joint instead of vice versa, would eliminate from the argument cases in which incision is notoriously unsatisfactory. We do not consider it true.

(9) On the subject of blood infections they remark that our cases had positive cultures far too long. We do not know exactly when the blood cultures became sterile, as we regarded it as unjustifiable to pester desperately ill children to find this out. But the remarkable thing is that Mr Trueta and Dr Agerholm "have not tested many cases" themselves and say vaguely that the "second culture has been sterile" without saying when this second culture was taken. As to the differences between our percentages of positive cultures and theirs, the one of us who has made a long study of this subject is convinced that the difficulties of avoiding staphylococcal contamination from the skin are much greater than is generally realized. He believes it is quite futile to compare series of these cases unless the technique is extremely accurate and exactly the same for both.

(10) On dosage they must have looked up our references and consequently know that our scale has been worked out by one of us at the request of the Medical Research Council in 1944 in the days of shortage of penicillin. We have subsequently found that though stepping up the dose improves laboratory tests it does not

imp o e clinical results and we consider duration of treatment far more important than high concentration of penicillin. What better test could this dosage have stood than this series of unselected cases over a period of three years? Yet they can say that they wonder how much has penicillin really affected this series? Our only reply to this is that the surgeons concerned wish to disclaim the implied but unmerited compliment.

Finally let us say that our paper was written as the record of an imperfect but we thought interesting and encouraging piece of work. We did not wish to criticize the work of others nor to lay down principles of treatment, considering our experience far too small. But it is implied all through the letter of Trueta and Agerholm that we should have done better to have used the methods of incision and primary suture they recommend. Very well then, how and why? It seems to us that if we had done so all our cases would have had major operations, which some of them would have stood very badly. They would have large scars, many involving joints. Their joints would be stiffer and their muscles more wasted. On the analogy of Mr Trueta's published cases, several of them would have discharging sinuses. What exactly has he got to urge on the other side?

We regret that in the absence of Mr T Twistington Higgins we have not been able to consult him on this letter, but we feel he would agree in essence with it—We are, etc

MARTIN BODIAN

London WC1

Intestinal Fusospirochaetosis Simulating Cholera

SIR—Menon in 1945 reported four cases of diarrhoea and severe pain in the abdomen, associated with the presence in the faeces of large numbers of *Treponema vincenti* and *Fusiformis fusiformis*. The following case report is of interest as it showed signs and symptoms suggestive of cholera, associated with intestinal fusospirochaetosis and responding to arsenical treatment.

CASE REPORT

A Hindu male railway porter aged 30 years was admitted to Lawley Hospital, Coonoor, on March 15, 1946, at 5.45 p.m. as a case of suspected cholera. The history given was that since 3 a.m. that day he had vomited several times and had a number of loose watery motions. He was admitted moribund, in a state of collapse. The pulse was imperceptible. The patient was very restless due to muscular cramps of great severity and was in a state of acute dehydration. He had not passed any urine since morning. On admission he was given adrenaline 1 ml and atropine 1/100 gr (0.65 mg) subcutaneously, hypertonic saline 500 ml intravenously, and essential oil mixture with kaolin.

March 15, 1946, 8 p.m. Condition slightly better, pulse perceptible. March 16, 8 a.m. Very restless pulse failing. Hypertonic saline with glucose, 500 ml IV, adrenaline and atropine repeated. 10 a.m. Still very weak, drowsy, not passed urine. Hypertonic saline 500 ml IV repeated, essential oil mixture repeated. 6 p.m. Condition poor, pulse 132, not passed urine for last 38 hours. Hypertonic saline 500 ml repeated.

Laboratory report on faeces. Microscopically, marked cellular exudate present. *E. histolytica* vegetative or encysted forms, Charcot Leyden crystals and ova of intestinal parasites not found. Large numbers of *Treponema vincenti* and a few *Giardia intestinalis* vegetative forms found. Culture *Vibrio cholerae* and intestinal pathogens not isolated.

In view of the successful therapeutic results previously obtained by ilic use of arsenical preparations in similar cases a dose of NAB 0.3 g was given intravenously at 6 p.m. with the following result. March 17. Condition much better, passed urine after 48 hours anuria, pulse 78. Put on stovarsol, one tablet twice daily. Discharged cured on March 26.

Inquiries regarding previous history elicited the information that the patient had recurrent attacks of diarrhoea though never of such severity during the previous two years. When seen eight months after this attack the patient reported that he had had no subsequent attacks and had been carrying on his normal work as a railway porter.

Points of unusual interest in this case are the severity of the symptoms, the persistence of anuria despite hypertonic saline treatment and the response to a single injection of NAB.

The author is indebted to Lieut Col M L Ahuja M.D., DPH IMS Director Pasteur Institute Coonoor, for his advice and help and to Rio Shih Dr K V N Nair Civil Surgeon Coonoor for his interest and kindness in furnishing the case history and progress report of the case—I am, etc.

The Teaching of Medicine

SIR—It was with much interest that I read Dr Edwin Bramwell's able defence (May 24, p. 741) of the *Edinburgh Postgraduate Lectures in Medicine*. He rightly insists that the day of the published clinical lecture is not passed and that 'the clinical lecture affords an opportunity to express and emphasize the art as contrasted with the science, an aspect of medicine which, as many clinicians will agree, often does not receive in our teaching nowadays the attention which it demands'. It is singularly appropriate that the editorial of the May edition of the *Post Graduate Medical Journal* discusses the question of clinical teaching as follows:

The good teacher is born, not made, and however wide the opportunities in the shape of access to unlimited clinical material, however advantageous the freedom from financial embarrassment provided by the altered circumstances incidental to the new regime when once the provisions of the Act are implemented, it will always be true that the value of his teaching will depend mainly on his personality and on his power of keeping contact with his students and of anticipating their individual difficulties with a readiness to meet the pupils on their own ground. This quality has been exemplified at its best in the great teachers of the Edinburgh Schools about the middle of the last century, the period at which, perhaps it may be said that that school was at its zenith. It may be observed here that these men although not fettered by any hard and fast regulations in respect to private practice were appointed primarily to their several posts in virtue of their fitness as teachers, and that the discharge of their functions in this respect was regarded by the School and University as a first duty. It is, however, pertinent to note that those of them whose success in this academic field was outstanding appear to have enjoyed an equal reputation among their private patients as men whose practical advice was to be valued, and indeed it was for this reason that it was sought and that their success in the ordinary sense of the word was assured.

Again, in his presidential address to the Section of Medicine of the Royal Society of Medicine, Dr Maurice Davidson states that 'medicine to day is at the cross roads. Like other human activities it is being stultified by unrelated knowledge, and like our entangled civilization as a whole it is losing to some extent the power of judgment, the virtue of discernment, the faculty of ascertaining truth by comparison of facts and ideas. With the outlook that has crept insidiously into our teaching schools to day not only is there a very real danger of losing this faculty but the students are being so herded into watertight compartments by purists with little or no clinical training that they fail to appreciate that it is just that clinical research at the bedside that is the most vital part of their education. Instead of walking the wards they are apt to be found wandering vaguely amidst a maze of cells. As we look back across the years to recall some of those lesser known teachers of our student days we must be greatly impressed not merely with what they taught us, but especially with how they taught us to think and, not least, to feel. These were the men who presided at the autopsy and correlated the clinical findings with just that broad general knowledge of pathology that was necessary for the better understanding of the patient, who existed as a human being and not as a piece of mouldy cheese.

The great teaching hospitals with their mighty tradition still maintain their reputation as centres of pregraduate teaching yet, because they have succeeded in being only distinct instead of 'distinct and yet united' under the wise guidance of their own clinical directors elected by themselves, medicine has been more and more encroached upon by an academic tide which forces the student to retire from the bedside into a world of books in order to cram for examinations which are often far removed from the practical world in which he is preparing to enter. One big correcting influence here would be that his work and standing throughout his career as a clinical student should count more in the way of marks than the final examination. What a pity, too, that he is not apprenticed to a good general practitioner during some part of his clinical course.

The Goodenough report on postgraduate education makes it clear that London has failed to attract as many postgraduate medical students even from the British Commonwealth as have centres on the Continent of Europe or in the United States of America. The main cause it says, "As Sir William Osler pointed out as long ago as 1911, has been lack of organization and cohesion. The facilities are there, men of outstanding distinction in their various subjects are there but the organization

has remained deficient despite the special efforts made to improve it during the period between the two wars." Actually, any lack of organization which exists clearly results from the lack of cohesion, which in turn depends upon too much of the petty parochialism that pervades the medical world throughout the country to day. One of the best ways of overcoming this would be to have an interchange of teachers from the various medical schools in the British Isles, and later (as has already been instituted in other scholastic circles) from the United States of America as well. The stimulating effect of this contact would be remarkable in itself and not least a broader and more fraternal concept of medicine would be engendered.

Though the statement that the really great clinical teacher must be born is doubtless true, the production of the average good clinical teacher is the all-important aim in preparing the foundation for this work. Not only must he be chosen from that point of view, but the special system of education which is now being adopted should include a broad cultural training, and this is most important, for it takes much more than a good mechanic to make a good physician—I am, etc.,

Bristol

FREDERICK SUTTON

Planning for Health

SIR—May I strongly support Dr Learoyd's protest (June 7 p 827) against the anonymity of planners in general and of those in Norfolk in particular? I myself took boys of the 1st Litcham Scout Troop camping on his Diglea Camp at Snettisham Beach before the war, and to suggest that anybody's health could be injured by camping there is so ridiculous as to border on the suspicious. It must be one of the healthiest sites in the country.

I have ascertained that the planning officers' bombastic sentence quoted by Dr Learoyd—a sentence of death to many a summer holiday—emanated from the County Offices, Norwich, and it is therefore pertinent to ask whether the county M.O.H. or any of his staff took part in suppressing this well-established camp on health grounds. If so, did they act on hearsay and local reports of non-medical men, or did they actually visit the site? If the latter, what was the date of visit, where can one see a copy of their report, what was the camping experience of the M.O. concerned, and who pulled his leg and misinformed him that the land was liable to flood? If this sounds like a questionnaire, may one not put the boot on the other leg for once?—I am, etc.,

E Dereham Norfolk

ERIC PUDDY

Medicine in the United States

SIR—I have just had the opportunity of visiting some medical and endocrine centres in the U.S.A., and venture to record very briefly a few outstanding impressions. Interest in the welfare of, and friendship for, Great Britain is enormous. Everywhere I went, and especially at the Annual Meeting of the Association for the Study of Internal Secretions, the cordiality, warmth of greeting, and reception were only interpretable on the basis of an individual being privileged to act as a channel of communication for Anglo-American friendship.

In my own field of endocrinology the United States constitute a vast field of amazingly fertile activity, and the current investigations are of great interest and originality. At the Massachusetts General Hospital and the Memorial Hospital, New York, I saw several cases of thyrotoxicosis treated by radioactive iodine given in a single dose by mouth. The eight-day isotope is now used and comes by air from a central station at Tennessee. The results are conclusively successful in exophthalmic goitre and in toxic adenoma, although the large nodular goitres with pressure symptoms are still thought more suitable for surgery. In simple thyrotoxicosis the goitre ceases to be palpable, and there is considerable shrinking of a toxic adenomatous goitre. Results in malignant thyrotoxic goitres are less satisfactory, as in some cases both the primary growth and the metastases may fail to "take up" the radioactive iodine. It is unlikely that the method will be generally used for some years as the possible development of late effects from radioactive substances is not yet ascertained. As yet no evidence of such untoward effects—e.g., induced malignancy—is forthcoming.

In general, hospitals of the big cities tend to be very large and imposing, and, as many have been built within the last thirty years, they contain exceptionally adequate laboratory and research accommodation. Even so, in some cases the latter is not sufficient to meet the progressive encroachment of the basic and ancillary sciences on medicine. One of the most attractive and efficient units I met with, however, is the Peter Bent Brigham Hospital, of Boston, with only 250 beds.

A welcome feature, by no means unknown in this country, is the close association between physicians, surgeons, clinical pathologists, morbid anatomists, and radiologists. Sometimes collaborative sessions were organized on a weekly or bi-weekly basis, or a clinician would start off his rounds in a room adjacent to the post-mortem room, where pathological specimens from the previous day's surgical operations or from necropsies, if any, could be inspected under comparatively aesthetic conditions, and representatives of investigatory departments attended in suitable cases by arrangement. As an example of the ready availability of biochemical information I would point out that a reliable flame photometer permitted assays of sodium and potassium concentrations in serum and urine within a few minutes.

It should be pointed out, however, that in spite of the exploitation of all modern ancillary methods nowhere have I seen a greater awareness of the psychosomatic approach, or more kindness, sympathy, and individual attention and understanding than that received by the patients in even the largest of the American hospitals I visited—I am, etc.,

S. L. SIMPSON

* On radio-iodine some points made by Prof Robley D Evans, of the Massachusetts Institute of Technology, in his lecture at the Royal Institution, were summarized in a recent annotation (June 21, p 894)—Ed. B.M.J.

State Medical Services

SIR—Without wishing to enter the lists either *pro* or *contra* State medical services, surely to attribute "a growing and already appreciable dearth of specialists" in New Zealand to the ten-year existence of a partial State medical service leaves out of consideration the effect of the war on the desire and opportunity for such training. A very considerable proportion of the younger men must have been in the Armed Services for a considerable proportion of the ten-year period and hence in large measure have been prevented from taking training that would qualify them as specialists. Furthermore, I believe I am correct in assuming that a large proportion of New Zealanders who do take higher qualifications do so in the U.K., and conditions existing from 1939 down to the present time were and still are such as to discourage private travel, to say the least. Another point, mentioned by Mr Porritt (*St Mary's Hospital Gazette*, 1947, 53, 54), but not by Sir Ernest Graham Little (May 3, p 611) is the "immediate financial lure to the newly qualified." This is indeed a point as the specialists are out of the State Medical Service and must presumably depend on fees. If they were in the Service at a higher rate of remuneration than G.P.s, the assured higher financial rewards would operate as an incentive to qualification as specialists. At the moment all that can logically be inferred is that New Zealand practitioners prefer an assured income in the State Medical Service to the uncertain income of private practice as specialists. This surely is of itself no condemnation of a State medical service.

Here in Canada, in Saskatchewan, we too have a partial State Medical Service. I understand there are many imperfections in that service. However, one point worthy of note is that there is a provision for regular postgraduate courses of study for those in the Service to enable them to become more proficient and to qualify as specialists if they so desire. Some not all specialists are in the scheme, which has only been in operation a short time. Here in Ontario the present trend is a little different. In a recent plebiscite of the medical practitioners of Ontario specialist and otherwise over 70% declared themselves in favour of prepaid medical and surgical care and the Ontario Medical Association, which conducted the plebiscite is taking an active interest in getting the scheme going although it is not itself operating it. I am not of course confusing prepaid medical care with a State medical service, which are totally different things.

With Mr Porritt's other conclusions I have no issue to take but except them is observed facts also the inference that they are due to the existence of a State medical service. I also of course accept as a fact his statement that there is a growing and appreciable dearth of specialists but not his nor Sir Ernest's inferences from that fact—I am etc,

Aldershot

S J NAVIN

International System of Weights and Measures

SIR—Dr J M Hamill (May 17 p 693) points out some obscurity in my previous letter (May 3, p 613) may I attempt to clarify this? The criterion of significance that I intended to apply was that the number produced by the measurement should differ observably according to whether the unit used was the cm³ or the ml. In normal laboratory practice the difference between cm³ and ml is so slight that it is quite submerged under the normal errors of measurement.

Dr Hamill says, The description of units of measurement should depend upon the units actually used. But it is in practice frequently impossible to decide uniquely what units have been used. The unit to be attached must then depend on other considerations.

The practical processes of measurement differ radically for most quantities (the principal exceptions are mass and length, and the best examples the electromagnetic quantities) from that used in the definition. The fundamental definition often stipulates complicated processes which are impossible to perform accurately without elaborate precautions. Therefore actual measurements are made with reference to substandards or calibrated instruments. The former are either quite arbitrary or depend on a particular quality of a particular substance. All are ultimately measured at infrequent intervals by reference to the absolute definitions. It must be admitted, if practical metrology is to be possible, that a comparison with a substandard is a good measurement in terms of any unit in terms of which the substandard is known to the required accuracy.

Some of the substandards are officially recognized (examples of such are the "international ohm" and the "litre"). There is therefore the choice of more than one unit for the quantity. The substandard may either be considered as a mere stage towards the fundamental unit, or as a unit in its own right. Thus, though the immediate measurement of a volume may be a volume-volume comparison and be expressed in litres, it may, if desired immediately be converted to and quoted as cm³ or gallons on multiplication by the appropriate factors. Volume is by no means the only example of this ambiguity, and all others must be treated similarly, or individual treatment justified. Dr Hamill has not attempted the latter, nor adopted the former—I am, etc,

Dorking Surrey

HARRY V STOKES ROE

Services Medical Examinations

SIR—I note that the Minister of Defence stated in the House of Commons on June 4 (Medical Notes in Parliament June 14, p 868) that miniature radiography of the chest was carried out, in the Navy, when a person was entered or as soon as practicable afterwards. A-ray of course detects many lesions that cannot be identified without its aid. All of the cases will have been examined prior to entry by National Service Medical Boards and accepted. They will therefore have an unassailable claim for pension. It appears to me that a great deal of public money would be saved by conducting the essential mass radiography prior to entry—I am etc,

London NW1

H SEARLE BAKER

Infectious Ectromelia in Wild Mice

SIR—I note that in the annotation headed 'Vaccinia and Ectromelia' (May 24 p 729) you state. It is unfortunate that little or no evidence is available as to the natural occurrence of ectromelia in wild mice or other rodents. May I draw your attention to a communication by Dr R Whitehead and myself published in the *Journal of Pathology and Bacteriology* 1933 37 253 and entitled 'Outbreaks of Infectious Ectromelia in Laboratory and Wild Mice'—I am etc

Cambridge

C A MCGAUGHEY

POINTS FROM LETTERS

Land of Excuses

DR BRUCE WILLIAMSON (San Marino, California) writes. I received my M.D. here in California and later took the Edinburgh Triple Board and the conjoint D.P.M. I practised near London from 1937 to 1941, at which time I was embodied into the Army, serving five years. With the background of this experience, taken together with first hand knowledge of medical education and practice in the States I might perhaps be forgiven for certain criticisms. Healthwise, England is a land of excuses for the backward conditions that prevail, excuses that never quite convince. The disparity between the skill of the physician on the one hand and the primitive sanitation and poor nutrition on the other ever presents an unhappy paradox of failure on the part of the profession to accomplish its purpose. It would appear that the public has sensed its want and, like the Athenian democracy it is, is about to treat itself to the health for all schemes now purveyed by the Socialists. There would never have been serious support for the root and branch transformations upon which the Minister is now bent had there remained any material confidence in existing means for promoting the nation's health. In their defence the doctors could not point with any pride to comparative excellence of sanitation, nutrition, health education programmes, and the like. They blithely relegated such responsibility to the public health men, towards whom their attitude is competitive rather than co-operative. It is unbelievable how completely the conscience of physicians is allayed by the offices of that minute priesthood, the medical officers of health. If the new Minister now afflicts them, let them realize that never a robust but rather a decayed, national health supplied him the power he wields.

Tobacco

DR A G PANNET (London, S.E.6) writes. For over twenty years I have smoked tobacco purely for enjoyment without ever having regard to its therapeutic value. This unconscious drug taking has so warped my judgment that I now value tobacco more than silver and pay, out of my taxed income to a Government apparently reluctant to receive it, an impost of some 3s 5d per ounce for the privilege of continuing my enjoyment—or should it be indulging my vice? I am sorry to learn that, on matters concerning tobacco, tobacco smokers are exceedingly untruthful, but your correspondent could, by taking a little trouble and examining the figures intelligently, verify from published figures that he was grossly in error in stating that one third of the American loan is being spent on tobacco. In fact our expenditure on American tobacco for home consumption in the first year of the American loan will represent less than 7% of our total drawings on the loan.

A "Medical Certificate"

DR JAMES O'GRADY (Swinton, Manchester) writes. Dr E Rowland Williams (May 31, p 785) refers to an objectionable form of "medical certificate" which is demanded by some insurance companies in connexion with claims under their "sickness and accident" policies. He rightly states that furnishing a reply to all the questions many of which have no bearing on the patient's actual illness, gives the company a free report on the patient as a "life." May I suggest a simple remedy? All the questions which have no real bearing on the illness for which the patient is claiming compensation should be answered, very simply, "not relevant." At the same time the patient should be advised to threaten legal proceedings against the company if the legitimate claim is not met.

Pruritus Ani as an Allergic Condition

DR G L DAVIES (Hove, Sussex) writes. Is it not possible that the clue to the pruritus of Dr E M Fraenkel's patient (June 7, p 823) is contained in the words "The skin proved to be allergic to skin disinfectants"? Some makers of toilet paper make much ado of the fact that their toilet paper contains some kind of disinfectant. One imagines that the frequent application of such toilet paper to a more or less perpetually moist area such as the perianal region would be enough, in certain predisposed people to set up a troublesome pruritus.

The "Pemmican" in China

Surgeon Lieutenant J M CLIFF (Hong Kong) writes. We all appreciated your efforts during the fuel crisis, which showed enterprise that is sorely lacking in other spheres of life at home. The first number of the Pemmican *BMJ* reached me in North China about ten days after it had left London.

Medical Library

Prof F C PYBUS (Newcastle upon Tyne) writes. I would like to assure my friends, including the writer of the sympathetic note under "Nova et Vetera" in your issue of May 31 (p 768), that my collection is intact and that the Sothebys' sale was of duplicates etc.

Obituary

LEONARD FINDLAY, MD, FRCP

Dr Leonard Findlay died at the age of 69 at his home in Surrey on June 14, and by his death British paediatrics has lost one of its outstanding physicians and a pioneer in the modern methods of investigation into the diseases of children.

Born and educated in Glasgow, Dr Findlay came of a family which had contributed much to the cultural life of his native city. He graduated in 1900 and proceeded MD four years later. Early in his career he became specially interested in paediatrics and soon came to devote his whole time to this special branch of medicine. He was admitted a Fellow of the Royal Faculty of Physicians and Surgeons of Glasgow in 1914. In 1919 he was appointed to the newly created lectureship in medical diseases of infancy and childhood at Glasgow University, and in 1924, when the Samson Gemmell Chair of medical paediatrics was established, he was the first to occupy it. In 1930 he resigned in order to carry on a consulting practice in London. He then became physician to the department of children's diseases at Radcliffe Infirmary, Oxford, and to the Princess Elizabeth of York Hospital for Children. He was elected FRCP in 1936.

Dr Findlay was an eminent clinician trained in the old school, where one's powers of observation were regarded as of more importance than a newfangled test. Yet there was no one more ready to adopt recent advances than he, and he remained until his retirement an exponent of modern medicine. His contributions to medical knowledge were important and numerous and gained for him an international reputation. In association with the late Prof P. Noel Paton he published an extensive series of articles on tetania parathyreopriva and also a special report for the Medical Research Council on poverty, nutrition, and growth. It is for his writing on rickets, however, that he will be best remembered, and although, as it turned out, his theory was not substantiated, he deserves credit for having stimulated an interest in a disease which has now all but disappeared from our large cities. He published books on congenital syphilis and rheumatic infections in childhood, and re-wrote John Thomson's *Textbook on Diseases of Children*.

Dr Findlay was a past president of the British Paediatric Association, an honorary fellow of the Medical Society, Budapest, and a corresponding member of the Paris Society of Paediatrics. He was an honorary member of the American Paediatrics Society and a director of the Child Welfare League of Red Cross Societies at Geneva. He had been a member of the British Medical Association for forty years and was president of the paediatrics section at the annual meeting in 1924. As a teacher and colleague, he was most stimulating. Students owe much to his wisdom in establishing paediatrics in the University of Glasgow as a compulsory course and laying the foundation for its wider appreciation as an integral part of the training of doctors. In the wards he was always full of enthusiasm and ready to impart his knowledge to the juniors. He dearly loved an argument, and often, it seemed to some of us, was not particular on which side he argued. Nevertheless, his facts were well marshalled and especially at the bedside his knowledge and wisdom stood out.

We regret the passing of this engaging personality, and those who knew him best will always remember him as a kindly sympathetic man at heart and be grateful for the help and stimulation he gave us. To Mrs Findlay and his two daughters we extend our sympathy.

CECIL WALL, DM, FRCP

Dr Cecil Wall, consulting physician to the London Hospital and to the Brompton Hospital, and a distinguished medical historian, died at his home in London at the age of 77 on June 19.

Reginald Cecil Bligh Wall came of a medical family. His grandfather was Dr A. B. Wall and his father was in practice in Bayswater. His mother was the daughter of James Luke, PRCS, FRS. Educated at Bradfield College, at Queens

College, Oxford, where he was Fitzgerald Exhibitioner, and at the London Hospital, he graduated B.M., B.Ch. in 1898, proceeding D.M. in 1902. During his Oxford days he distinguished himself as a rifle shot, winning the National Rifle Association's bronze medal in 1891. He held resident posts at the London Hospital, and acted for a few years as physician to the Eastern Dispensary and the Poplar Hospital. He was then elected to the honorary staff of his old hospital and to that of the Brompton Hospital for Consumption and Diseases of the Chest. He was elected FRCP in 1908, and by this time had established himself as a consultant and a teacher. He became a member of the board of the faculty of medicine and of the board of advanced medical studies of London University. He was also on the board of the Oxford medical faculty and dean of the Brompton Hospital Medical School. An examiner in medicine at Oxford and in London, he was Bradshaw Lecturer in 1920 at the Royal College of Physicians and gave the Schorstein Memorial Lecture at the London Hospital in 1928. His Thomas Vicary Lectures at the Royal College of Surgeons in 1935 formed the basis of his *History of the Surgeons Company*. Published in 1937, this book dealt with the history of the Company from 1745 to 1800. The subject had been covered previously in Sir D'Arcy Power's 1886 edition of *South's Craft of Surgery*, but Dr Cecil Wall brought to light a great deal of additional material from the manuscript minute and account books of the Company. His purely medical writings are less well known and were mainly on diseases of the chest and on chorea. He was a member of council of the National Association for the Prevention of Tuberculosis and a trustee and member of council of his old school, Bradfield College.

Cecil Wall became the official archivist to the Society of Apothecaries after he had passed the Master's chair in 1932-3, as his father had done before him. Here again he devoted much of his time to the study of the Society's original records. In 1932 he published his account of "The London Apothecaries' their Society and their Hall," which formed part of his wider studies of the relations between barbers, surgeons, apothecaries, and physicians, and the systems of licensing in the eighteenth and nineteenth centuries. Some of the results of these researches were summarized in his Fitzpatrick Lectures in 1944. He was the first historian to give a full account of the Lambeth degrees in medicine and here, as in his other work, all his findings were based on study of contemporary manuscripts in the possession of the Royal Colleges and the Society of Apothecaries.

Dr Cecil Wall had been a member of the British Medical Association for some thirty-five years. He was vice-president of the section of tuberculosis at the annual meeting in 1928 and he served later on the committee on the relation of alcohol to road accidents. He represented the Society of Apothecaries on the General Medical Council from 1932 to 1940. He married Dorothy, the daughter of H. Innes Frigg and had one son and two daughters.

F. HOWARD HUMPHRIS, FRCPED

Dr Francis Howard Humphris, the radiologist, died at Bath on June 17 at the age of 81.

Frank Humphris was born at Croydon in 1866 and educated at Highgate School. He was a student at Edinburgh University and at University College Hospital. He took the conjoint diploma in 1895, and for the next three years he worked as a tutor at Brussels University, where he proceeded M.D. In 1900 he was elected a Fellow of the Royal College of Physicians of Edinburgh, and for ten years he was in practice in Honolulu. At this time he became president of the Hawaiian Territorial Medical Society. Returning to London in 1908, he was for six months clinical assistant in the x-ray and electrotherapeutic department of the West London Hospital. He served in the R.A.M.C. with the rank of major in the first world war and was mentioned in dispatches. Towards the end of the war he was with the Egyptian Expeditionary Force reorganizing the radiotherapy departments of military hospitals in that theatre. In 1920 Dr Humphris took the Cambridge diploma in medical radiology and electrology, and he was on the consulting staff of the East and West Molesley and Hampton Court Cottages.

Hospital. He did a great deal of work for the St John's Clinic and Institute of Physical Medicine and was a Commander of the Order of St John of Jerusalem. He was on the staff of Christ's Hospital and was the author of three books on electrotherapy.

Dr Humphris had been a member of the British Medical Association for over fifty years. He was a representative at annual representative meetings on no fewer than ten occasions, and he was at one time chairman of the Westminster and Holborn Division. He had been president of the Irish Medical Graduates Association, and he was also president of the Brussels Medical Graduates Association. A past-president of the Hunterian Society, he was also a member of the Roentgen Society and of the West London Medico-Chirurgical Society.

L. K. writes: This is just a personal appreciation of the man and his charm. Frank Humphris went through life with a constant smile on his face, which smile he was willing to share with all his many and varied friends. He vividly and buoyantly often expressed, and gallantly acknowledged, his gratitude to life itself. I possessed for years his friendship, and I found his personality irresistible. As a host he was second to none—his great delight in life was 'throwing a party'. His concoctions—he called them cocktails—served in enormous glasses, were ever puzzling in their make up, with spices from the plains of Arabia, curious and exotic fruits from the shores of Honolulu, all mingled with unheard-of liqueurs. They were baffling in character, they were potent beyond words. As a chef, too, there was nothing to teach him. He delighted to help a lame dog over a stile, and in his hey day he helped many, and gave generously. As a raconteur, he was hard to beat, at his clubs and elsewhere, and he was a good mixer. He certainly was born to smile at life, and to move light-footed towards the twilight. *Heureux qui comme Ulysse a fait un beau voyage*.

Dr CHARLES WITTS, who died at the age of 62 on April 11, was educated at Hereford High School and received his professional training at Guy's Hospital. He held a number of hospital appointments in London until the outbreak of the first world war. As a captain, R.A.M.C., attached to the H.L.I., he served in France, was awarded the M.C. and was taken prisoner in the early months of 1918. He settled in practice in Edgbaston, Birmingham, and from 1939 he served on a medical board for national service and on the pensions board. A man of considerable clinical skill of sound judgment, and of terse wit, he was popular among his colleagues both at the medical boards and in the district.

Dr WALTER HENRY BRAZIL died on May 3 at his home in Coventry. Dr Brazil was born at Chorley, Lancashire, and was educated at Preston Grammar School and at Owens College, Manchester. He took the B.Sc. there and graduated M.B. in 1889, proceeding M.D. two years later. He then undertook a long voyage to Japan before starting in general practice in Bolton, where he worked for some years before moving to Coventry. He had been a house surgeon at the Manchester Royal Infirmary, and resident medical officer at St Mary's Hospital, Manchester, and it was during this period that he contributed a first short article to our columns in 1889. Dr Brazil was one of the best known practitioners in Coventry, and apart from his work his principal interests were in music, antiques, and the construction of model boats. He had been a member of the B.M.A. since 1890, and was chairman of the Coventry Division in 1927-8.

Dr JOHN SNALLEY DOCKRAY died at Bournemouth on May 27, aged 76 years. He graduated B.Sc. in 1890 and took the degree of M.B., Ch.B. with first-class honours at Manchester in 1897, proceeding M.D. a year later. He then joined an old-established practice in Bishop's Stortford, Hertfordshire, and continued his work there until 1926, when he was succeeded by his son, Dr J. Vernon Dockray. His outstanding ability and strong personality, combined with a handsome and dignified mien, led to the building up of a large general practice which soon included many local appointments among them that of physician to Bishop's Stortford Hospital. He was a member of the British Medical Association for twenty-five years and was acting honorary secretary of the Hertfordshire Branch in 1930 and president in 1931-2. He was the representative at the A.R.M. each year from 1929 to 1935. Dr Dockray was one of the original members of the Hertfordshire Insurance Committee on which he served for twenty-five years

and acted as chairman for a period of four years. In addition, he was a member of the Urban District Council from 1904 to 1937 and again from 1940 to 1944. He was also for several years a member of the Hertfordshire County Council and a county magistrate, and he took an active part in furthering the interests of the local Conservative Association. On his retirement from active practice he lived in Bishop's Stortford and latterly in Bournemouth. He is survived by his wife, who nursed him devotedly during a steady deterioration in health, and by his son who is now in practice at Stradbroke after a long period of war service.

Medico-Legal

THE LIMITS OF DENTAL PRACTICE

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

Dentistry, unlike medicine, is restricted to registered practitioners. The Dentists Act, 1921, section 1, prohibits the performance of any such operation and the giving of any such treatment, advice, or attendance as is usually performed or given by dentists, and also lays down that any person who performs any operation, or gives any treatment, advice, or attendance in connexion with the fitting, insertion, or fixing of artificial teeth is deemed to practise dentistry. A shop assistant, a dental mechanic who was not on the Dentists Register, told a customer that her teeth were all the same size and looked too artificial and could be improved. She suggested that the customer should exchange the teeth, and offered to supply six plastic teeth for three guineas and gold filling for other teeth to take away the artificial look. The Dental Board prosecuted her for unlawfully practising dentistry and her employers for aiding and abetting her. The Southport justices found that she had not practised dentistry, and the Board appealed to the High Court.¹

The Board admitted that a dental mechanic may, without committing any offence, repair a denture which is brought to him. Lord Goddard, Lord Chief Justice, said that it obviously followed that he may make a repair which involves replacement of teeth affixed to the denture. There is no reference to a 'denture' in the section. He could not think that because a dental mechanic said to a customer that her looks could be improved if her teeth were not all the same size and offered not to make a denture, not to interfere with the existing denture but to replace teeth on the denture with others of a different colour or size, the mechanic was infringing the section. Mr Justice Atkinson recalled a case² in which an unregistered person had made and fitted a set of teeth and sued for their value, the court had held that for an infringement of the law as it then was the operation, attendance, or advice must be directed to the condition of the mouth and to the treatment of the living person, the law was not broken by something done upon a set of false teeth. Since that decision the definition of the offence had been enlarged, but the meaning of 'operation' and 'advice' had not been extended. If Parliament had intended to make it an offence to work on an existing denture it would have put appropriate words in the Act. The word 'in connexion with the fitting, insertion, or fixing of artificial teeth' meant the doing of these things in connexion with the mouth itself. Merely altering an existing denture was not covered by the section. Whether advice was given was a question of fact in each case. The shop assistant had merely suggested that there should be an alteration in the denture and there was evidence to justify the conclusion of the magistrates that she had not given advice. Mr Justice Oliver, agreeing, said that he would have come to a different conclusion if the magistrates had found that any part of the fitting to the patient's mouth was to be affected by the advice given, but they had not.

The line limiting dental practice therefore seems to lie at the limit of the patient's person. Presumably an action which requires the patient for its performance is dental practice, but one which merely requires the denture is not.

Regulating the Blood Prothrombin Level

ACETOMENAPHTHONE and MENAPHTHONE

Vitamin K analogues which raise the prothrombin level in hypoprothrombinaemia

For the prophylaxis and treatment of haemorrhagic states arising from hypoprothrombinaemia—

- Neonatal and post-extraction haemorrhage
- Menorrhagia, purpura and urticaria
- Obstructive jaundice and biliary fistula
- Sprue and idiopathic steatorrhoea

DICOUMARIN (DICOUMAROL)

A synthetic anticoagulant which depresses the blood prothrombin level

For the prophylaxis and treatment of thrombosis and embolism, particularly after operations—

- Puerperal thrombosis and thrombophlebitis
- Coronary thrombosis and pulmonary embolism
- Cavernous sinus thrombosis
- Post-traumatic arterio-thrombosis

VITAMIN C B.D.H.

(Ascorbic Acid B.P.)

Vitamin C is recommended for accelerating convalescence, promoting early and satisfactory healing of wounds, burns and fractures and for reducing susceptibility to infection. Further, the vitamin C requirement is high during pyrexial infections, it should be prescribed freely and generously, therefore, for patients with high temperatures.

Vitamin C, administered collaterally with arsenical and mercurial compounds, also helps to mitigate toxic effects and augment therapeutic efficacy. Further information is available on request.

Medical Notes in Parliament

PENICILLIN BILL

The Penicillin Bill was considered in Committee in the House of Commons on June 18. On Clause 1 Mr JOHN EDWARDS, Parliamentary Secretary to the Ministry of Health, moved to insert a proviso intended to meet the criticism that undesirable nursing homes not carried on under professional supervision might administer the substances or preparations to which the Bill applied. Answering Mr R S Hudson, Mr Edwards said he understood that direction meant instructions usually given in writing but which might also be given by word of mouth. The amendment was agreed to.

Mr DEREK WALKER-SMITH moved to leave out paragraph (f) of Clause 1, which provided that penicillin would be available to any Minister of the Crown or Government Department. Mr EDWARDS resisted the proposal, and it was defeated by 146 to 42. The House then agreed to an amendment indicating in what circumstances the substances or preparations covered by the Bill might be dispensed more than once or more than three months after the date on which the prescription was signed. It brought the provisions for prescriptions covered by the Bill into line with those for poisons under the Poisons Rules.

On the motion that the Clause as amended stand part of the Bill, Lord HINCHINGBROOKE said housewives under the Bill were denied the opportunity of going to a chemist's shop and securing penicillin as a right, yet a Minister of the Crown had that right.

Sir HARTLEY SHAWCROSS said that where the phrase 'Minister of the Crown' was used in the Bill what was intended was a Minister of the Crown not acting privately but for the Crown, as head of his department. Mr Linstead asked whether the Attorney General could name any Minister whose need of penicillin for the purposes of his department would not be met by the words 'Government Department' alone? The Clause as amended was then ordered to stand part of the Bill.

"Secret Remedies"

On Clause 2 Mr CHRISTOPHER SHAWCROSS moved to insert the words "medicinal substances" and thereby to enlarge the control given to the Minister of Health beyond the present range of antimicrobial organic substances produced by living organisms. He said control should extend to such other medicinal substances as the Minister after consultation with the Medical Advisory Council might prescribe. The Minister should be given control over all other medicinal substances which might be exploited in the way penicillin would be exploited if it was not controlled. Although he had said on Second Reading that the patent medicine industry was probably the largest and most harmful and certainly the most shameful, racket ever organized by private enterprise, that remark was not meant to be a criticism of all patent medicines. What he attacked were the quack remedies like iodine belts and penicillin lipsticks. He hoped the Minister would make a statement on the Report Stage or later to show whether he would take control of a major evil which had never properly been dealt with by Parliament for the last thirty years. He recalled the famous *Secret Remedies* published by the British Medical Association. More recently in Lancashire, a county where this racket was rife, Prof. Henry Cohen had in public speeches and writings campaigned against this devastating evil. Still more recently a report drawn up by the Pharmaceutical Society had been presented to the Minister of Health by Mr Linstead and was under consideration. Although the report as a whole was confidential extracts had been published by the Pharmaceutical Society and showed that this was a topic which should be dealt with urgently.

Mr J EDWARDS said there were still widespread abuses connected with proprietary remedies which ought to be checked, but those substances were in a different category than the ones which the Bill sought to control. The substances covered by the Bill might give rise to serious danger to the general public if maladministered whereas undesirable proprietary remedies were not dangerous to the public at large. While Mr Bevan was favourably disposed to further legislation dealing with proprietary remedies there was no prospect of early action on this point. Mr Edwards then moved to insert a proviso that where the regulations prescribed a substance produced by living organisms they might include any substance of identical or similar chemical properties which was not produced by living organisms. The amendment was accepted and the Clause as amended was ordered to stand part of the Bill.

On Clause 4 Mr R S HUDSON pointed out that the Bill said penicillin had the meaning assigned to it by the regulations for

the time being in force under the Therapeutic Substances Act, 1925. He asked why penicillin should not be defined in the Bill itself.

Mr EDWARDS admitted that he could not produce the definition at present in use. Definition by reference to another Act was a routine practice in the definition of substances and was also used in order that it could be altered as scientific knowledge on the substance changed. The words in the Bill contained a mechanism by which these therapeutic substances could be redefined. After further discussion Mr Edwards read the definition made in accordance with the Act of 1925.

"Any anti-infective acid produced by *Penicillium notatum* whether obtained from *Penicillium notatum* or not, any salt or derivative of any such acid and any solution containing any such acid, salt, or derivative, being an acid, salt, or derivative, or a solution thereof, prepared for parenteral injection."

The Committee then agreed to the amendment proposed by Mr Edwards, and Clause 4 as thus amended was ordered to stand part.

Clause 5 (Application to Northern Ireland) was also ordered to stand part with an amendment proposed by Mr Edwards which provides that the Ministry of Home Affairs for Northern Ireland shall have power to enforce the Act and for that purpose to employ the inspectors under the Pharmacy and Poisons Act, 1925. Clause 6 was ordered to stand part of the Bill without amendment and the House agreed to a new Clause empowering the Pharmaceutical Society of Great Britain to enforce the provisions of the Bill and for that purpose to employ their inspectors. Mr Linstead pointed out that in Scotland the actual prosecution would be by the Procurator Fiscal although the inspectors could obtain evidence.

After further discussion the Bill was reported as amended. A motion to adjourn the debate was defeated and Mr Edwards moved the Third Reading. This was agreed to.

Universities and Colleges

UNIVERSITY OF OXFORD

In a Congregation held on May 1 the following degrees were confirmed:

B.M.—E. G. Walsh N. V. B. Marsden R. E. A. Hansen J. F. W. Redwood
*C. E. M. Wenyon *G. B. Rooke *C. G. Elliott *Rachel F. Shackleton

‡ Includes puerperal fever for England and Wales and Eire

EPIDEMIOLOGICAL NOTES

Paratyphoid Outbreak

There has been a small outbreak of paratyphoid B infection in the mining village of High Spenn Durham. The first case was reported to the medical officer of health of Blythdon U.D. on June 5. This was a boy of 14 with a clinical picture of continued pyrexia, delirium, and some neck rigidity. There have since been 8 cases of proved paratyphoid B infection (4 in infants). The date of onset of the disease was probably between May 28 and June 1. Search for a source of infection showed milk to be the link connecting these cases. Specimens of faeces were taken from (a) All contacts, (b) family of a milk distributor, (c) family of a milk producer, (d) all workers (male and female) on the farm, (e) family of an ice cream merchant. Samples of milk, water, and ice cream were also examined. All these specimens proved negative with the exception of that from the milk producer's mother. She had been found to be a carrier in 1932.

Investigation showed the probable route of infection to be the towels with which the cooler and churns had been wiped. Steps have been taken to sterilize the dairy and all utensils, and the old lady has been barred from living on the farm. Organisms from the carrier and from the cases are of the same phage type.

An interesting point, not yet fully investigated is that a few cases which occurred in Gateshead earlier in the year were found to be of the same type, and apparently some of this farmer's milk went to a pasteurizing plant in Gateshead from which the cases had obtained their milk supply.

Smallpox

No further cases have been detected at Burnsley C.B. and Wakefield C.B. since the last removals on June 4, and the period of surveillance of contacts has now expired. It would be premature, however, to assume that the outbreaks in these districts have terminated.

The only focus of smallpox known to be active is at Bilston U.D., Staffs, and here the position is less satisfactory. A new generation of cases appeared on June 17, and since then 8 patients have been admitted to the smallpox hospital. The diagnosis is at present doubtful in 6 of these, and the unquestionable cases come from a single household not previously affected, nor under surveillance. Two other patients have been admitted to the Bilston Smallpox Hospital from Willenhall U.D. and Dudley C.B. respectively. If the diagnosis is confirmed the source of infection in the former is known to have been at Bilston but the appearance of the disease at Dudley cannot at present be explained.

Polio-myelitis

There were 31 notifications of polio-myelitis in the week ending June 14 in England and Wales. This is higher than usual for the time of year, and an upward trend is expected. Prevalence has been unusually low since 1938, and, generally speaking, notifications have not risen above 30 a week nor has a significant rise appeared until the end of July. Possibly the exceptionally warm weather at the end of May has had something to do with the present increase.

There have been 9 cases in Barrow in Furness and other cases in Bedfordshire, Worcestershire, and South London. As is usual, any direct connexion between cases has been the exception rather than the rule. About 15% of the cases are adults. Clinically there is considerable variation in severity and cases of respiratory paralysis requiring treatment in an iron lung have occurred. At Barrow-in-Furness 2 pregnant women are involved, and 3 of the patients showed persistent meningeal signs as an outstanding feature.

Discussion of Table

In England and Wales further falls were recorded in the notifications of scarlet fever 156 and acute pneumonia 45. An increased incidence was recorded for measles 1,221 and whooping-cough 393.

The largest increases in the notifications of measles were in Essex 245, Lincolnshire 178, London 136 and Gloucestershire 129. The largest falls were Glamorganshire 113 and Somersetshire 86. Although the number of cases of measles fell in Glamorganshire, a rise of 168 was recorded for the remainder of Wales.

The only significant changes in the local trends of whooping-cough were increases in Lancashire 64 and Surrey 60. Small decreases in the incidence of scarlet fever were recorded in most areas of the country, the largest fall was Lancashire 35. The

chief feature of the returns for diphtheria was a decrease of 11 in Durham

Notifications of paratyphoid were the largest for six months, and the 16 cases were distributed over ten counties. The only large centre of dysentery was London, with 14 cases. The distribution of the 7 cases of smallpox was Yorkshire West Riding Barnsley C B 2, Wakefield C B 1, Staffordshire, Bilston M B 4

In Scotland an increased incidence was recorded for acute primary pneumonia 50 and dysentery 21, while a decrease was reported for measles 32, cerebrospinal fever 25, and scarlet fever 21. The rise in the incidence of pneumonia was fairly widespread, in Glasgow the increase was 35. The largest increase in cases of dysentery was Edinburgh 11.

In Fire the only fluctuations of note in the returns were an increase in the incidence of measles 22 and a decrease in the notifications of diarrhoea and enteritis 15. Both these alterations in trend were mainly due to the experience of Dublin C B.

In Northern Ireland infectious diseases were less prevalent and small decreases were recorded for most diseases.

Quarterly Returns for Scotland

The birth rate during the March quarter was 24.1 per 1,000. This is the largest rate for any quarter during recent years and was 6.4 above the average of the five preceding first quarters. Infant mortality was 63 per 1,000 registered live births and was 13 below the average for the corresponding quarters of 1942-6. Stillbirths were equivalent to a rate of 32 per 1,000 total births. The general death rate was 17.2 per 1,000, which was 0.9 above the rate for the first quarter of 1946 and 1.4 above the five years' average. The death rate from all forms of tuberculosis was 91 per 100,000, that from respiratory tuberculosis was 73, these rates were 9 and 7, respectively, above the rates for the March quarter of 1946 and 4 and 6 above the five years' average.

Week Ending June 14

Notifications of infectious diseases in England and Wales during the week included scarlet fever 833, whooping-cough 2,062, diphtheria 195, measles 10,796, acute pneumonia 380, cerebrospinal fever 49, acute poliomyelitis 31, dysentery 48, paratyphoid 12, typhoid 4. No case of smallpox was notified.

Medical News

School and Life

The Report of the Central Advisory Council for Education has been issued as a pamphlet with photographic illustrations entitled *School and Life* (H.M.S.O. 2s 6d). Discussing the school medical service the report suggests for its improvement that, owing to the present shortage of medical personnel available, the medical examinations should be raised in quality rather than in quantity. It advocates more comprehensive supervision of school children, including consultation between doctors and parents and teachers, together with better access to and keeping of medical records. Accommodation for medical inspection in schools should be improved, as well as facilities for treatment in hospitals and clinics. Commenting on the need for what it calls a positive approach to health, the report quotes a young engineer as saying that "the greatest need of all is not greater medical service but better health services in the form of wholesale extension of school playing fields, swimming pools, fresh milk, fruit, meals, etc." and adds that special training of doctors, nurses, and teachers is essential. It emphasizes elsewhere the need for suitable buildings, play grounds, and meals, referring to Mr Churchill's observation, "We shape our buildings, and afterwards our buildings shape us."

Harveian Society

The Harveian Society of London held the first Buckton Browne dinner since 1939 in the Royal College of Surgeons on Thursday, June 19. The President of the Society, Dr Maedonald Critchley, received the many distinguished guests. Admiral of the Fleet Sir James F. Somerville proposed the toast of 'The Harveian Society of London' and the President replied briefly. The toast of the guests was proposed by Sir Cecil Wakely, and Lord Moran and Sir John Anderson replied.

Haematological Research

Oxford University has accepted a grant of £50,000 from the Nuffield Foundation, to be paid over a period of ten years, to maintain a haematological research unit at the Medical School.

Society of Medical Officers of Health

At the annual luncheon of the Society of Medical Officers of Health on Friday, June 20, Sir Allen Daley, the President, proposed the toast of the guests. His speech, which was well received, was described by Mr Aneurin Bevan, who replied, as "barbed by knowledge and delivered with intention." Mr Bevan said that his present discussions with the representatives of the medical profession were being conducted in "a diminuendo of acrimony." He thought that in the future medical officers of health would form important links between the regional boards, the health committees, and the executive councils. Replying to the Minister, Sir Allen Daley made two points. He suggested that perhaps the time had come when the Society of Medical Officers of Health might be promoted to that select group blessed with the "Royal" designation. He also pointed out that any expansion of the work of medical officers of health would depend on up to date knowledge of morbidity in all diseases and not only in connexion with notifiable diseases.

Royal Sanitary Institute Prizes

The Royal College of Physicians has given the first of the Memorial Travelling Scholarships to the British Empire Nurses War Memorial Fund "as a tribute from the doctors to their colleagues the nurses." Lord Moran, President of the College, announced that the Royal College of Physicians was providing a scholarship of £350-£400 for seven years. Viscountess Mountbatten of Burma has offered a scholarship on similar terms "as a small tribute to the magnificent service rendered by nurses and midwives both in this country and throughout the Empire during the past years." The national appeal for the fund is for £250,000 to provide (after the furnishing of a nurses' war memorial chapel in Westminster Abbey) a fund for postgraduate travelling scholarships for nurses and midwives of the British Commonwealth and Empire. The nurses and midwives of the Empire have already raised £35,000 in the year since the fund was launched by the *Nursing Mirror*.

Encyclopaedia

The 1946 and 1947 volumes of the *British Encyclopaedia of Medical Practice* recording medical progress have been issued under the editorship of Lord Horder, together with the cumulative supplements for these years (Butterworth and Co. 42s for each pair of "Medical Progress" and "Supplement"). Authorities in the various branches of medical science provide critical surveys of the recent advances in Part I of the volumes of "Medical Progress," and developments in pharmacy and therapeutics are reviewed in Part II, and in Part III abstracts from the recent literature are given. The "Cumulative Supplements" summarize the recent literature to bring the main body of the work up to date.

Empire Rheumatism Council

The Scientific Advisory Committee of the Empire Rheumatism Council has appointed a subcommittee to re-start the British branch of the Ligue Internationale contre le Rheumatisme. Dr W. S. C. Copeman is chairman and national representative of the branch, Dr G. D. Kersley treasurer, and Dr Oswald Savage secretary. The European branch of the Ligue will hold a congress at Copenhagen on Sept. 3-6, under the presidency of Prof. Cai Holten, and the American Rheumatism Association will sponsor an international congress for rheumatic diseases in the U.S.A. in 1949. Those wishing to become members of the British branch of the Ligue should apply to Dr G. D. Kersley, 6, The Circus, Bath.

Hygiene Prizes

The Royal Sanitary Institute announces that prizes will be offered during 1947 for competitions on (1) practical improvement of appliances or inventions for dwelling houses, and (2) atmospheric pollution or the ventilation of buildings and its effect upon human health. For the first of these essay competitions, the John Edward Worth Prize of £40 is offered, the second competition, which gives a choice of subject this year, will be for the John S. Owens Prize of £25. The general conditions applicable to the competitions can be obtained from the secretary of the Institute, 90, Buckingham Palace Road, London, S.W.1.

British Council Bursaries

British Council bursaries have been awarded to Dr David Honore, of the surgical department, Liège University, who is studying thoracic surgery and anaesthetics at Brompton Hospital, London, for four months, and to Dr A. Ennuvier of Radiotherapie Fondation Curie, Paris, who is at the Royal Cancer Hospital, London, studying radiotherapy for six months.

Dental Caries in Sweden

The interesting fact has been established that in Sweden the incidence of dental caries decreased considerably during the war, the decline ranging about 15%. The lowest incidence has been found to occur in the provinces round Lake Mälaren, in central Sweden, where the drinking water contains fluorine.

Fellowships in Diabetes

The Diabetic Association is to support and encourage new work on diabetes by creating Lund Research Fellowships in Diabetes up to the value of £750 a year. These fellowships are named after the generous donor. The Diabetic Association has established a subcommittee of medical and scientific experts to allocate the funds in the most promising direction.

Medical Superintendents Society

The annual general meeting of the Medical Superintendents' Society was held at Birmingham on June 13, when Dr D. Campbell Suttie was installed as president. The annual dinner of the society was held the same evening with Sir William Scott Douglas, Permanent Secretary to the Ministry of Health, as the principal guest.

The Friends in China

Mobile teams of the Friends Service Unit are carrying out a successful campaign against kala-azar in Honan, China. A preliminary report on the treatment of about 3,000 patients with intravenous neostam is hopeful that the disease will shortly be brought under control.

Film on V D

The United States Public Health Service has produced a film (running time 20 minutes) on venereal disease, suitable for showing in clubs and schools, entitled *A Message to Women*. 16 mm prints in colour (price \$75) may be obtained from Precision Film Laboratories, 21 West 46th Street, New York City.

War Service

The President of the Czechoslovak Republic has conferred the decoration of the Order of the White Lion, Fourth Class, upon Dr David Robert Rigg, in recognition of services during the war.

COMING EVENTS**Cavendish Lecture**

Mr H S Souttar will deliver the Cavendish Lecture on "Physics in the Life of a Surgeon" before the West London Medical-Chirurgical Society at Kensington Town Hall on Tuesday, July 1, at 8.30 p.m.

The NAPT

The National Association for the Prevention of Tuberculosis has arranged for a conference on tuberculosis in all its aspects to be held in London on July 8-10 at the Central Hall, Westminster, S.W.1. The Duchess of Kent will open the conference. Mr Bevan will speak at the first day's meeting on the N.H.S. Act and its effect on tuberculosis control and treatment. Sessions will include discussions on sanatorium design, rehabilitation, and the psychology of tuberculosis. Problems arising in the British Commonwealth will receive particular attention, and representatives from all Dominions and Colonies have been invited. Further particulars may be obtained from the NAPT, Tavistock House North, Tavistock Square, London, W.C.1.

Microbiology

The Fourth International Congress for Microbiology will be held in Copenhagen on July 20-26, 1947, under the auspices of the International Association of Microbiologists and will be composed of the following nine sections: General Microbiology, Medical and Veterinary Bacteriology, Virus and Viral Diseases, Serology and Immunology, Variation and Mutation in Microorganisms, Plant Pathology and Mycology, Water and Soil Microbiology, Industrial Microbiology (Dairy and Food Microbiology), and Industrial Microbiology (Alcoholic and other Fermentations). Registration fee will be 30 Danish kroner which will not include the cost of a banquet ticket or a Report of the Proceedings of the Congress. Congress Office, Kommunehospitalet, Copenhagen, telegraphic address: Microbiolog, Copenhagen.

Cancer Research Congress

The fourth International Cancer Research Congress will be held at St. Louis, Missouri, U.S.A. from Sept. 2 to 7, with headquarters at Jefferson Hotel, 415 North Twelfth Street, St. Louis. The congress is sponsored by the Union Internationale Contre le Cancer and the American Association for Cancer Research, with the assistance of other organizations and individuals interested in promoting cancer research.

Society for Endocrinology

The following officers were elected at the annual general meeting of the Society for Endocrinology on May 29: Chairman of Society, Dr A. S. Parkes; Secretary, Dr S. J. Folley; Treasurer, Dr C. W. Emmens; Editor of the Society's *Proceedings*, Prof. S. Zuckerman; Members of Committee, Dr P. M. F. Bishop, Dr C. H. Gray, Mr P. C. Williams, Prof. F. G. Young.

DIARY OF SOCIETIES AND LECTURES

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields. W.C.—Thursday, July 3, 6.15 p.m. Ophthalmology Lecture by Prof. Arnold Sorsby. Measurement of the Living Eye. Friday, July 4, 6.15 p.m. Bernhard Baron Lecture by Prof. John Beattie. Physiology of the Post-operative Period.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS, 58 Queen Anne Street, W.—Friday, July 4, 3 p.m. William Meredith Fletcher Shaw Memorial Lecture by Prof. F. J. Browne. Hypertension in Pregnancy, 5 p.m. Biennial Scholarship (Sterility) Lecture by Mr J. R. Stallworthy. Fact and Fantasy in the Study of Female Sterility.

ROYAL SOCIETY OF MEDICINE

Annual Meeting of the Society—Tuesday, July 1, 1.30 p.m.

APPOINTMENTS

The National Society for the Prevention of Blindness, New York, announces the appointment of Dr Franklin M. Foote, assistant professor of public health and preventive medicine at Cornell University Medical College, as executive director in succession to Mrs. Eleanor Brown Merrill, who has retired.

Mr R. Victor Howell has been appointed general secretary of the Empire Rheumatism Council in succession to Sir Frank Fox, O.B.E., who has retired. Mr Howell has also assumed office as secretary to the Heberden Society.

Dr P. S. Bell has been appointed an Official Member of the Legislative Council of the Nyasaland Protectorate.

Prof. R. C. Garry has been appointed Regius Professor of Physiology at Glasgow University to succeed Prof. E. P. Cathcart, who is retiring.

Prof. Garry won the Brunton Memorial Prize in 1922 and was later appointed lecturer in experimental physiology at Glasgow University. In 1933 he was appointed Head of the Physiology Department of the Rowett Research Institute at Aberdeen and lecturer on the physiology of nutrition at Aberdeen University. Since 1935 he has occupied the Chair of Physiology at St. Andrew's University. Prof. Garry is well known for his researches on dietetic problems; he was a member of the subcommittee on Nutrition of the Scientific Advisory Committee to the Department of Health for Scotland and he is the editor of the *British Journal of Nutrition*.

Dr R. B. Robertson, M.B.E., succeeds Dr R. Stewart Miller as Medical Director of the Mental Hospital at Asfuryeh, near Beirut.

Dr Miller, who took up his appointment in 1934, was previously at the Egyptian Government Mental Hospital at Khanka and was made Commander of the Order of the Nile for his services. Dr Robertson, who has been working recently at the East Sussex County Mental Hospital, gained a wide knowledge of the Near East during the recent war when he was at Cairo and speaks colloquial Arabic.

MIDDLESEX COUNTY COUNCIL.—The following appointments are announced at the hospitals indicated in parentheses: *Obstetrics*: Muriel Rose, M.E. (Redhill County Hospital, Epsom); A. W. Purdie, M.B. Ch.B. FRCP (North Middlesex County Hospital, Edmondeston).

NEWCASTLE UPON TYNE. ROYAL VICTORIA INFIRMARY.—The following appointments are announced: *Honorary Surgeon*: J. Brumwell, F.R.C.S. *Assistant Physicians*: H. G. Miller, M.D. and H. A. Dewar, M.D. *Assistant Surgeons*: J. D. Rose, F.R.C.S. and J. D. T. Jones, M.S. F.R.C.S. *Assistant Surgeon to Gynaecological Department*: F. Stabler, M.D. F.R.C.S. F.R.C.O. *Associate Surgeons to Gynaecological Department*: W. Hunter, M.D. and E. Way, M.R.C.S. L.R.C.P. *Assistant Surgeons to Throat, Nose and Ear Department*: J. I. M. Black, M.D. F.R.C.S. and J. L. Reid, M.B. B.Ch. *Assistant Surgeon to Ophthalmic Department*: L. H. Lake, M.B. B.S. *Associate Surgeon to Ophthalmic Department*: Margaret Ranken, M.B. B.S. *Associate Physicians to Children's Department*: E. E. Wright, M.D. C. Davison, M.D. and F. J. W. Miller, M.B. B.S. *Clinical Bacteriologists*: C. A. Green, M.D. *Head of Department of Anaesthetics*: E. A. Pask, M.B. Ch.B. *Assistant Radiologist*: B. D. Houston, M.B. B.S.

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice authenticated by the name and permanent address of the sender and should reach the Advertisement Manager not later than first post Monday morning.

BIRTHS

ANNAR.—On May 29, 1947, at Cardiff, to Dr Doreen Annar (née King, wife of Dr. Marshall Annar, a sister for John—Rosemary Doreen).
BATES.—On June 18, 1947, at Leicester, to Teddy (née Edwards), wife of D. A. Priestley Bates, a daughter.
DAVISON.—On June 20, 1947, to Ida, wife of Dr. M. H. Armstrong Davison of Newcastle upon Tyne, a daughter.
FROOFE.—On June 10, 1947, to Peggy Barrington (née Lister), the wife of Dr. Kenneth Froome of 5 Town Close Road, Norwich, a daughter.

MARRIAGES

FRASER—THWAITES.—On June 6, 1947, at Inverness, Iain Alexander Fraser, M.B. Ch.B. to Betty A. Thwaites, Q.A./R.
LAWLESS—BANNERMAN.—On June 11, 1947, in Kensington, Desmond Lawless, O.B.E. M.B. B.Ch. B.Sc. D.P.H. to Ail Bannerman, M.R.C.I.

DEATHS

BROWN.—On May 8, 1947, at 15 Shrub Avenue, Mansfield, William Hunt Brown, M.B. Ch.B. D.P.H., aged 56.
LITHELAND.—On June 16, 1947, at 19 Wimborne Road, Bournemouth, Henry Litherland, L.S.A., the beloved and devoted husband of Doris G. Litherland, M.R.C.S. L.R.C.P., aged 79 years.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Rh Incompatibility and Pregnancy

Q—*It could one be justified in interrupting pregnancy in the case of an Rh negative woman married to an Rh-positive man after the usual history of one normal child followed by one stillbirth or neonatal death due to erythroblastosis foetalis?*

A—It is not justifiable to interrupt a pregnancy in an Rh-negative woman merely because of the possibility of producing another child affected by haemolytic disease. If the husband is heterozygous for Rh, then the wife has an equal chance of a normal unaffected child at each subsequent pregnancy. The Rh genotype of the husband should be ascertained so far as is possible, but the exact genotype cannot always be determined from the study of his blood alone, as more than one genotype gives the same serological reactions. The correct genotype may sometimes be determined by studying, in addition to the husband's blood, that of his parents or of his children, and this may enable one to distinguish, for example, between R_1R_1 (CDe/CDe) when he is homozygous and all subsequent children will be affected, or R_1R' (CDe/Cde) where half of the children would probably be unaffected. If the woman produces children with icterus gravis or congenital anaemia there is a reasonable prospect of saving the child by immediate transfusion, especially modern replacement transfusion, but if the child is hydropic no known treatment is of any avail. The justification of early induction of labour lies in the frequency of foetal death in the last week or so of pregnancy, and is probably the correct procedure if the child is large as delay in parturition is dangerous. In such a case one might be guided by the amount of antibody in the maternal serum and whether it was of the agglutinating or blocking type, the latter being of graver prognosis. Sterilization should not be hastily undertaken, and certainly not until a detailed serological examination of the husband and wife and their family has been carried out. In the present pregnancy all preparations should be made to transfuse the baby promptly with Rh-negative blood in the hope that it may be saved by this means.

Sterilization and the Law

Q—*An epileptic girl aged 18 has been away at a special school for the last seven years. The parents now wish to have her home but hesitate because she is lacking in moral sense and has been the victim of a sexual assault. Is sterilization permissible?*

A—It is impossible to answer this question with authority. It is constantly asked, and the answer is always that the law governing the sterilization of women is obscure. The fact remains that no medical practitioner has ever been sued or prosecuted for performing sterilization of a mentally defective (or indeed of any other) woman, and the risk of legal consequences in this case is therefore slight.

Calciferol for Surgical Tuberculosis

Q—*Is the treatment of bone and gland tuberculosis by massive doses of vitamin D₂ of any value? Is there a danger of renal damage or other toxic effects from this treatment and what measures of control are advisable?*

A—The value of large doses of calciferol in osseous and glandular tuberculosis is not yet proved, but the results of this treatment have so far been encouraging. Toxicity is seen in 50% of cases, the early signs being depression, nausea, and epigastric discomfort. Renal damage does not appear to be common but it is unwise to use this treatment on completely recumbent patients. It is also dangerous in the presence of active lung disease. While under treatment with calciferol the patient should be observed closely, preferably in hospital. A watch should be kept for toxic symptoms, and the erythro-

cyte sedimentation rate and blood calcium levels should be estimated regularly. A rising sedimentation rate or a very high blood calcium are indications for stopping the treatment.

Pulmonary Stenosis

Q—*Does the dilated pulmonary artery associated with isolated pulmonary stenosis ever show well-marked pulsation?*

A—In most instances congenital pulmonary stenosis is associated with other congenital cardiac lesions, usually with a patent foramen ovale or a defective ventricular septum, or both. In only 9 out of 110 cases collected by Abbott was pulmonary stenosis an isolated finding. Examples of isolated pulmonary stenosis are too rare for a generalization to be of value, but in the cases seen by the writer there was no pulsation on clinical examination. The radiological findings on this point are inconstant.

Paraldehyde Addiction

Q—*What are the clinical features of addiction to paraldehyde? What is the prognosis and is there any treatment likely to be effective? My patient aged 75 takes 2 to 3 drachms (8 to 12 g) of paraldehyde at night. She complains of inability to sleep without the drug, drenching sweats, chronic conjunctivitis with photophobia, and nasal catarrh.*

A—In the rare cases of true addiction to paraldehyde the symptoms may be indistinguishable from those of chronic alcoholism. Even delirium tremens has been reported. The prognosis of true addiction is bad, as it is for all drug addictions. In the case in point it appears that true addiction is not present, but rather a demand for a soporific. In view of the age and the small doses taken, why take steps to check the habit?

Recurrent Facial Herpes

Q—*What can be done with recurrent facial herpes in the distribution of the right maxillary division of the trigeminal nerve? My patient, a healthy woman of 34, has had an average of one to two mild attacks a year for the past fifteen years.*

A—It is of first importance to see that there is no local source of infection or irritation, such as paranasal sinusitis, dental or tonsillar sepsis, ear trouble, or an unerupted wisdom tooth. X-ray therapy locally (150 r at 80 kV at monthly intervals for three treatments) will sometimes stop recurrences. Arsenic by mouth in gradually increasing doses up to the limit of tolerance, over a period of a few weeks, may be employed. Autovaccination with fluid from the vesicles or vaccination with calf lymph has sometimes been successful, but the affection is often resistant to all measures.

Emanotherapy for Rheumatic Disorders

Q—*Is emanotherapy or spa treatment by radium emanation, for rheumatism and allied conditions an ethical line of treatment? Has it met with any marked success, and how does it differ from ordinary spa treatment? What are the risks, if any from drinking radio active water and of external applications of radio active ointment or liniments?*

A—Emanotherapy has been used in the treatment of rheumatism and allied conditions since the early days of our present civilization, albeit unwittingly, since it is only in more recent times that radio activity has been demonstrated in various spa waters. Originally the treatment consisted of baths or ingestion of spa waters, in the present century this has been extended by the use of inhalations and ointments, either of the naturally occurring radio-active water or of artificially manufactured solutions or ointments containing radium salts or radon. There is a large body of opinion which considers such treatment of value, but this is based for the most part on impressions and not supported by consistent scientific data, either by results or by rationale. Many spa waters do not contain enough radio activity to give a therapeutic effect, and further investigations are needed to establish the rationale of any effect before one may speak of low intensity radium therapy in connexion with springs with a low emanation content. The difficulties of such analysis are further complicated if the mental constitution of spa visitors is considered. The risks of the treatment at well-conducted spas are negligible. It would

take 1 500 million litres of the average spa water to reach a dangerous dose. Ointments containing radium salts may be dangerous but do not now seem to be used. Emano therapy is not included in the general regimen of treatment of rheumatic subjects in this country, spa treatment is used for the discipline incurred and for its value as a remedial agent in muscular re-education. Fitch, writing on mineral waters of the U.S.A. states that sciatica is curable by radio active treatment, if it is continued long enough, by baths and springs. Such a statement, reviewed in the light of modern pathology, leads to increased confidence in time, but not in radio activity, as a cure and such criticism is applicable to many aspects of this controversial subject.

Persistent Sinus after Resection of Rectum

Q—A woman aged 60 had an abdomino-perineal resection of the rectum for carcinoma five months ago. She has a left inguinal colostomy functioning normally. The perineal wound was treated in the usual way and the patient got up early so that the 'dead space' would be minimized by downward pressure. A narrow sinus about 4 inches (10 cm.) long persists in the rectal and anal region. The entrance is kept open with dilators and the sinus has been irrigated with saline, packed lightly with ribbon gauze and once or twice curetted but it shows no sign of healing. There is a slight mucoid discharge. What further treatment do you advise?

A—The discharge is not purulent, so it is unlikely that the cause of the persistence of the sinus is infection, the presence of mucus makes one rather suspicious of some communication either with mucous membrane or with a glandular secondary focus. The first thing to do is to demonstrate the whole extent of the track by taking a radiograph after the injection of lipiodol (or other suitable radio opaque substance) into the sinus, this might show unsuspected extension higher up the pelvis or even a fistula into the region of the posterior vaginal fornix. The next step would be to open up the sinus sufficiently to explore it with the finger so as to make sure there is no tag of silk ligature, or even a tiny strip of gauze at the bottom. If no sufficient cause be found, the local therapeutic effect of x rays might well be tried.

Bringing Up Baby

Q—To what degree is it permissible to 'thwart' a baby of 3 months? To amplify Instance 1—The child has just been fed and so far as one can tell free of further troubles. One wishes to put him down but he evidently wants company. Is one justified in putting him in his cot and establishing a rule that when he has been fed and received attention he is to be left? Will this help to eliminate conflict and make him happier—on the assumption that he will soon learn that he won't be picked up at that time of day or will his happiness be best served by according him his mother's love at his every demand? Instance 2—He wakes at 4.30 p.m. and is carried round for half an hour to amuse him. Mother then wants to put him down but he doesn't agree. Is it too early to establish discipline by putting him down even though he cries, or are his mother's protection, warmth and love to be accorded him at his every command? Perhaps my question amounts to this: Is an infant to be allowed to rule his parents?

A—The final sentence of this inquiry—Is an infant to be allowed to rule his parents?—suggests that the main problem may lie in this attitude that implies a rival status—Who shall rule? This and other phrases describing a baby of 3 months—he evidently wants company, doesn't agree [with his mother], at his every command—presuppose intellectual processes as yet undeveloped. Intellectually it is of course evident that an infant's reactions are conditioned only by his needs, which he expresses by crying, having no other language. Emotionally it is much more difficult to accept this fact, for the child's unhappiness, violently expressed, seems to his parents like a challenge though actually it is for their care that he cries. It is surely natural that since a child begins his foetal life as an extension of his father and mother after birth he still remains in their feelings as part of themselves—a biological attachment invaluable in evoking love and protection, but disturbing also when the 'demerol of infancy' becomes

involved in this identification. In this way the moral self condemnation irrationally aroused in the best of parents may become projected in their child.

In dealing with the baby who demands attention, it may help to regard the behaviour as objectively as any phenomena of disorder, to seek the cause and to treat it. It seems that there is a lack of satisfaction somewhere, and for this reason, although the baby's physical needs are well cared for, it is possible that he is conscious of over anxiety in handling or of lack of maternal warmth. Insecurity in those who look after him is quickly sensed by a baby, with consequent anxiety and distress. In this case his parents, who have taken the trouble to consult the *Journal* on his behalf, may by this token of good intent towards their child feel the confidence in themselves that they deserve.

Ingrowing Eyelash

Q—A male aged 40 has for two years had an ingrowing eyelash on the left lower lid which impinges on the eyeball and has to be plucked out. He does not wear glasses. Is there any way of preventing this eyelash from growing?

A—A single lash is best treated by electrolysis. This is likely to produce permanent epilation. A fine electrolysis needle attached to the negative pole is entered towards the root of the lash. The current used is 1 to 3 mA for twenty to thirty seconds. A bubble of white foam forms at the point of electrolysis. The procedure is best carried out after preliminary infiltration analgesia by 1 ml of 4% novocain. It is, however, possible to dispense with this.

NOTES AND COMMENTS

Ejaculatio Praecox—CONSULTANT writes: One of your recent questions (May 31, p. 794) was "What advice should be given to a healthy man, newly married, who ejaculates prematurely?" I have dealt with many of these cases and I find that in the majority of them some such advice as the following is of great assistance. What I say to the patient is something like this: "Premature ejaculation is of no consequence, you must train yourself for intercourse just as you would for any other activity. Have one intercourse early in the evening and do not worry about the premature ejaculation. Then take your wife out to dinner, the theatre, or a film and have a pleasant evening together. On returning home, you will find that a second attempt will be more successful. A third later the same night may be completely successful. This technique should be repeated twice a week, or perhaps even three times."

Birthday Honours—The names of Edwin Arthur Blok, L.R.C.P. & S.E.d., lately Assistant Director of Medical Services, Ceylon and Carol Jameson, F.R.C.S., F.A.C.S., Vice Principal, Missionary Medical College for Women, Vellore, North Arcot District, Madras, were omitted from the Birthday Honours published in the *Journal* of June 21 (p. 895). Dr Blok was appointed C.B.E. (Civil Division), and Miss Jameson was awarded the Kaiser-i-Hind Gold Medal for public services in India.

Correction—In the issue of June 14 (p. 859) the O.B.E. was incorrectly attributed to Prof. D. Murray Lyon.

INCOME TAX

Colonial Pension

H. asks whether a pension given for colonial medical service is regarded as earned or unearned income.

****** Under Sec. 14 (3) of the Income Tax Act, 1918, 'earned income' is defined as including "any income arising in respect of any pension given in respect of the past services of the individual in any office or employment of profit."

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: A110103. WESTCENT LONDON. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1 on receipt of proof. Authors overseas should indicate on MSS. if reprints are required as proof are not sent abroad. LIST OF ILLUSTRATIONS

SPECIAL PLATE

Basal cell Carcinoma at Site of Trauma (T G Reah)	inset between 406 and 407
Lateral Orbitotomy (H B Stallard)	inset between 406 and 407
Lipoid Pneumonia (R E Rewell)	inset between 406 and 407
Marrow Biopsy (D F Cappel and others)	facing 406
Parotidectomy (Hamilton Bailey)	facing 407
Teratoma of Testis Spontaneous Disappearance of Lung Metastases (J Ewart Schofield)	inset between 406 and 407

ILLUSTRATIONS IN THE TEXT

Adrenalectomy in Mental Disorder (E Cunningham Dax and others)	215
American Medical Association Centennial of (Morris Fishbein)	795
Anemia Persistens in a Breast-fed Infant with Erythroblastosis Foetalis (Rosemary Davies)	138
Anatomy Surgical of Vagina with Special Reference to Vaginal Operations (Wilfred Shaw)	477
Atmospheric Dryness a Simple Formula for Calculation of (R L Wynne)	528
Atropine Intravenous for Peptic Ulcer (Anastase Landau)	928
Bancroft Sir Joseph	470
Bethlem Royal Hospital	935
Carcinoma Basal-cell at Site of Trauma (T G Reah)	412
Chadwick Sir Edwin (1800-90)	63
Colour Index Calculation of (Ronald Elsdon Dew)	723
Copeman Sydney Arthur Mon kton	546
Cruise Sir Richard	74
Cystine Stones (W M Chesney)	912
De Morgan's Spots (A R Murison and others)	634
Digital Foreign Bodies in Spot welders (W A B Reynaud and Frederick Smith)	843
Diphtheria Faucal among Army Personnel in Belgium 1945 (I H Bolton and M J Pivaver)	373
Dislocation of Metatarsal Joints (W Douglas Park)	381
Recurring Spontaneous of Shoulder joint treated by an Appliance (Eric Coplans)	62
Duncan William Henry (1805-63)	62
Electro-convulsion Therapy Use of d-Tubocurarine Chloride and Thiopentone in (I A Hobson and Frederick Prescott)	445
Emphysema Surgical due to Compressed Air (A M Desmond)	842
Fever Relapsing in Cyrenaica (N F Coghill and others)	637
Fibrobloma Congenital of Cornea (K Mehta)	681
Folic Acid as a Therapeutic Agent (L S P Davidson and R H Girdwood)	587
Forceps Cutting Punch Biopsy (J Walter)	462
Surgical the Trap jaw Principle in (Sir Henage Ogilvie)	192
Gangrene Symmetrical in the African (Michael Gelfand)	847
Haemoglobin Concentration Changes in Acute Stage of Lobar Pneumonia (Margaret S Ferguson)	131

Haemostats Diathermy (Wilson Hey)	
Hepatic Hydatid Cyst causing Suprarenal Haemorrhage (L W Godfrey)	
Hopkins Sir Frederick Gowland	
Hydrocephrosis Temporary (Bruce Fowler and Eric Frankel)	
Inflator Taper Type for Anaesthetic Masks (A Owen Flood)	
Laryngoscope New for Anaesthetists (R L Soper)	
Lawson Sir Arnold	
Medical Experiments on Human Beings in Concentration Camps in Nazi Germany (Kenneth Mellanby)	
History in Postage Stamps	
Microscope Operating (A Brownlie Smith)	
Multihallucium (Ronan O Rahilly)	
Myiasis Intestinal an Unusual Case of (D S Sharpe)	
Myopathy with Spina Bifida (Ronald G Paley)	
Orbitotomy (Harvey Jackson)	
Oxygen Poisoning in a Man (Kenneth W Donald)	
Parotidectomy Indications and Results (Hamilton Bailey)	
Penicillin Simple Method of Estimating Penicillin and Other Bacteriostatics (J Fielding)	
Physiology of Vision Recent Advances in (H Hartridge)	
Prostate Complete Removal of (H H Souttar)	
Renal Disease Unilateral the Place of in Hypertension (Christopher Hardwick and Alec W Badenoch)	
Scrub Typhus Vaccine its Effect on 16 Cases incubating the Disease (W Thomson Walker)	
Shore Thomas William	
Simon Sir John (1816-1904)	
Smith Thomas Southwood (1788-1861)	
Sphygmomanometer Armlet as Tourniquet (R L Wynne)	
Spinal Wash outs in Treatment of Purulent Meningitis (J A Nissim)	
Splints for Fractured Noses (Michael C Oldfield and W R Roberts)	
Streptomycin Some Problems in the Titration of (J R May and others)	
Sulpha-combination —A New Principle (A Runc Frisk and others)	
Thoracoplasty Retractor (R Lambert Hurt)	
Trichlorethylene in Midwifery (Walter Calvert)	
Trichobezoar (F M Parsons)	
Trocar Sternal and Cannula (Hamilton Bailey)	
Trolley for Gas Cylinders (G O Cowdy)	
Tuberculosis Epidemiology of (John W S Blacklock)	
Twelve Toes (Ardeshir K Turner)	
Uterus Post partum Intra abdominal Separation of (J J S Wassenaar)	
Vitamin A in Infective Hepatitis (A D Harris and T Moore)	
Volvulus of Caecum (Ralph H Gardiner)	
Water and Salt Depletion (H L Marriott)	
Westmoreland House	
Whitfield Arthur	
Wright Sir Almoth	

INDEX TO VOLUME I FOR 1947

PLACERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate headings—for example, Brain and Cerebral, Heart and Cardiac, Liver and Hepatic, Renal and Kidney, Cancer and Carcinoma, Child and Infant, Gout and Thyroid. Subjects dealt with under various main headings in the JOURNAL have been set out in alphabetical order under their respective headings—for example, Annotations, "Correspondence," "Leading Articles," "Obituary," "Reviews," etc. Original Articles are indicated by the letter (O).

NOTE: The two Pemman issues follow page 1 and are paginated in the index 284a 284b
